Six marked pumas born on the study area that survived to adult ages exhibited philopatry. Five females established adult home ranges overlapping those of their mothers; 4 of those subsequently reproduced. One male was killed by a hunter within his mother's home range when he was 30 months old. We recaptured another male when he was 28 months old, 1.8 km north of his mother's home range; 1 week later he was killed by a hunter 3 km north of his mother's home range. Because of the short time he wore a radio-collar as an adult, we could not determine the extent his movements overlapped with his mother's home range. Both males may have also ranged off of

the study area, as did their mothers, after their cub collars quit functioning and we could no longer monitor their movements. Both of the males died 11.1 km and 12.8 km from the nurseries where they were initially marked.

Of 37 cubs surviving to the subadult stage in the reference period, at least 10 (27%; 9 males, 1 female) were known to have emigrated from the UPSA. Similarly, of 36 cubs surviving to subadult stage in the treatment period, at least 9 (25%; 8 males, 1 female) were known to have emigrated from the UPSA.

We collected data on 34 pumas (7 females, 27 males) that were born on the UPSA and dispersed from natal areas (Fig. 9). Four females and 24 males emigrated entirely from UPSA. Females dispersed an average of 30.7 km (95% CI = 23.2–38.2,

Figure 9. Pumas born, captured, and marked on the Uncompahgre Plateau Study Area (UPSA) Colorado, USA, 2004–2014, that later dispersed from their natal areas after separation from mothers. End points of their movements indicated by the ends of the arrows are to the last known locations.

range = 18.7–46.8). We determined dispersal endpoints for females when they were 17–44 months old (\bar{x} = 26.7, 95% CI = 24.7–28.8). Males dispersed longer distances than females, averaging 63.9 km (95% CI = 53.8–74.0, range = 17.7–104.1). We determined dispersal endpoints for males when they were 17–65 months old (\bar{x} = 33.1, 95% CI = 27.8–38.3).

We obtained data on 14 other independent pumas (8 females, 6 males) with unknown origins that were initially captured and marked on the UPSA but subsequently emigrated (Fig. 10). At their first capture, estimated ages of females averaged 21 months (95% CI = 17–26) and males averaged 21 months (95% CI = 17–25). Females moved on average 70.9 km (95% CI = 21.4–119.2, range = 18.4–214.1) from capture sites to endpoints. We found endpoints for the females when they were about 24–79 months old (\bar{x} = 33, 95% CI = 20–46). Males moved on average 190.5 km (95% CI = 76.4–304.6, range = 39.6–369.1) from capture sites to endpoints. Males were about 26–55 months old (\bar{x} = 39, 95% CI = 29–49) when we determined their endpoints. Pumas from this group made the farthest movements; 1 female and 1 male moved to northern New Mexico, 1 male moved to the eastern slope of the Rocky Mountains in Colorado, and 1 male moved to southern Wyoming.

Survival

Adults.—The adult survival data included 75 radio-collared individuals, with 32 (21 females, 11 males) monitored in the reference period and 61 (39 females, 22 males) monitored in the treatment period. Sixteen (10 females, 8 males) were monitored in both periods. The number of adult females and males monitored annually ranged from 10–22, and 6–9, respectively (Fig. 6B). Survival modeling resulted in 2 closely ranked models ($\Delta AIC_c < 2$) that accounted for 89% of the model weights. The top-ranked model indicated a period effect interacting with sex

Figure 10. Pumas of unknown origin captured and marked on the Uncompahgre Plateau Study Area (UPSA), Colorado, USA, 2004–2014, that later dispersed to locations outside of the UPSA. End points of their movements indicated by the ends of the arrows are to the last known locations.

(Table S2, available online in Supporting Information). Adult male annual survival was over 2 times higher in the reference period (0.96) than in the treatment period (0.40; Table 9). The estimate for annual adult female survival was also higher in the reference period (0.86) than in the treatment period (0.74). The evidence ratio from AIC_c weights indicated the top-ranked model had 1.2 times the support of the second-ranked model with adult male survival interacting with period and adult female survival constant. In this model adult male annual survival varied in each period as in the top model, and adult female annual survival was 0.78 over both periods. The remaining 7 models in the 9-model candidate set had weak to no support ($\Delta AIC_c > 4$).

Subadults.—The subadult survival sample included 75 individuals with known-fates: 22 (8 females, 14 males) in the reference period and 53 (19 females, 34 males) in the treatment period.

Table 9. Top-ranking survival models (difference in corrected Akaike's Information Criterion [ΔAIC_c] < 2) for adult and subadult pumas, and estimated adult annual and subadult stage survival rates with 95% confidence intervals, 2005–2014, Uncompahgre Plateau, Colorado, USA.

Life stage	Model ^a	Sex	Reference period survival (95% CI)	Treatment period survival (95% CI)
Adult ^b	Sex × period	Male	0.96 (0.75–0.99)	0.40 (0.22–0.57)
		Female	0.86 (0.72–0.94)	0.74 (0.63–0.82)
	M × period (F constant)	Female	0.96 (0.75–0.99)	0.40 (0.22–0.57)
Subadult ^c	M × period (F constant)	Female	0.78 (0.70–0.85)	
		Male	0.92 (0.57–0.99)	0.43 (0.25–0.60)
	Sex × period	Female	0.68 (0.43–0.84)	
		Male	0.92 (0.57–0.99)	0.43 (0.25–0.60)
		Female	0.63 (0.17–0.89)	0.70 (0.39–0.88)

^a Period = reference (no hunting) vs. treatment (hunting allowed). M = male. F = female.

^b Sample sizes of adult pumas included 11 males and 21 females in the reference period and 22 males and 39 females in the treatment period.

^c Sample sizes of subadult pumas included 14 males and 8 females in the reference period and 34 males and 19 females in the treatment period.

The number of subadult females and males monitored annually ranged from 1–6, and 1–14, respectively (Fig. 6B). Survival modeling resulted in 2 closely ranked models ($\Delta AIC_c < 2$) that accounted for 77% of the model weights (Table S3, available online in Supporting Information). The top-ranked model indicated period as an important factor explaining male survival and constant female survival. Subadult male survival was 2 times higher in the reference period (0.92) than in the treatment period (0.43). Subadult female survival was 0.68 over the 2 periods (Table 9). The evidence ratio from AIC_c weights indicated that the top model had 2.6 times the support of the second-ranked model of sex interacting with period. Subadult male survival varied in the 2 periods the same as in the top model, and subadult female survival was variable but similar in the reference (0.63) and treatment (0.70) periods. The remaining 7 models in the 9-model candidate set had weak to no support ($\Delta AIC_c > 2$).

Cubs.—The cub survival data included 118 radio-collared cubs: 55 cubs (28 females, 27 males) from 32 litters in the reference period, and 63 cubs (27 females, 36 males) from 45 litters in the treatment period. The number of females and males monitored annually ranged from 5–14, and 5–17, respectively (Fig. 6B). The estimated \hat{c} for the most parameterized cub survival model we could use (i.e., period \times sex) was 1.55, indicating that the fates of siblings were not independent. We documented numerous occasions of this phenomenon. In the reference period, 7 radio-collared siblings in 3 litters died at the same time from infanticide. In addition 3 non-collared cubs in 1 litter starved after the mother was killed for depredation control. In the treatment period, 19 radio-collared siblings in 8 litters died at the same time from a variety of causes including depredation control (3 cubs in 1 litter), vehicle strike (2 cubs in 1 litter), infanticide (7 cubs in 3 litters), and starvation (7 cubs in 3 litters). In addition, 2 non-collared cubs in 1 litter died from infanticide.

Modeling results indicated 4 models with a $\Delta QAIC_c < 2$; all 4 supported models contained the covariate for mother status alive

or dead (i.e., mother status) and accounted for 78% of the model weights (Table S4, available online in Supporting Information). These models indicated that survival of the mother during cub dependence was the most important factor to cub survival. Evidence ratios using $QAIC_c$ weights indicated the top model with the covariate mother status alone had 2.5 times the support of the second-ranked model, sex + mother status, and 2.7 times the support of the third- and fourth-ranked models, period + mother status and sex \times period + mother status, respectively. In the top model, the survival estimate of cubs with living mothers (0.51) was over 3 times higher than of cubs whose mothers died (0.14; Table 10). With sex and mother status as main effects, survival estimates of male and female cubs (0.54 and 0.49, respectively) with living mothers were 3 to 4 times higher than for cubs of those sexes (0.16 and 0.12, respectively) with mothers that died. With period and mother status as main effects, survival estimates of cubs with living mothers in the reference (0.53) and the treatment (0.49) periods were over 3 times higher than of cubs with mothers that died in the reference (0.16) and treatment (0.13) periods. With sex interacting with period and mother status as a main effect in the reference period, survival estimates of male (0.74) and female (0.37) cubs with living mothers were 2 to 7 times higher than for cubs of those sexes (0.38 and 0.05, respectively) with mothers that died. In the treatment period, survival estimates of male (0.44) and female (0.59) cubs with living mothers were 3 to 6 times higher than for cubs of those sexes (0.08 and 0.19, respectively) with mothers that died. There was no support for period alone explaining variation in cub survival ($\Delta QAIC_c = 5.8$).

Reproduction

Adult females on the UPSA produced litters in the months of March to September. Data on 66 birth dates revealed that births increased rapidly in May and June, peaked in July, declined slightly in August and rapidly declined in September. No live births were detected from October through February (Fig. 11).

Table 10. Top-ranking survival models (difference in corrected quasi-Akaike's Information Criterion [$\Delta QAIC_c$] < 2) for puma cubs monitored in the reference (27 males, 28 females) and treatment (36 males, 27 females) periods, and the estimated stage survival rates with 95% confidence intervals, 2005–2014, Uncompahgre Plateau, Colorado, USA.

Model ^a	Covariates	Survival (95% CI)
Mother status	Mother alive	0.51 (0.35–0.66)
	Mother dead	0.14 (0.03–0.34)
Sex + mother status	Male	0.54 (0.33–0.71)
	Female	0.49 (0.27–0.67)
	Male	0.16 (0.03–0.41)
	Female	0.12 (0.02–0.34)
Period + mother status	Reference	0.53 (0.31–0.71)
	Treatment	0.49 (0.27–0.69)
	Reference	0.16 (0.01–0.49)
	Treatment	0.13 (0.03–0.33)

	Female, Reference	0.37 (0.14–0.62)
	Male, Reference	0.38 (0.03–0.79)
	Female, Reference	0.05 (0.00–0.33)
	Male, Treatment	0.44 (0.19–0.68)
	Female, Treatment	0.59 (0.27–0.82)
	Male, Treatment	0.08 (0.01–0.30)
	Female, Treatment	0.19 (0.03–0.47)

^a Mother status = mother was alive or dead when individual cubs were dependent. Period = reference (no hunting) vs. treatment (hunting allowed).

Figure 11. Monthly puma conception and birth frequency from 19 May 2005 to 30 September 2014 ($n = 66$ litters of 33 females). We examined 60 litters at nurseries when cubs were 25–45 days old; we confirmed 4 litters by tracks of ≥ 1 cubs following radio-collared mothers and 2 litters by remains of cubs of 2 radio-collared mothers when cubs were ≤ 45 days old, Uncompahgre Plateau, Colorado, USA.

We estimated minimum and maximum gestation for 17 litters of 13 females. Gestation length medians were 91–92 days and averages were 90.4–91.8 days (95% $CI_{min.} = 89.1$ –91.6; 95% $CI_{max.} = 90.8$ –92.9). Considering an average 92-day gestation period and the distribution of birth months on the UPSA, puma breeding activity spanned the months of December to June, increased in February, and peaked March through May when 71% of the litters were conceived (Fig. 11).

The average age that 14 females (12 approximately aged by our methods, 2 of known age) gave birth to their first litters was 32 months (95% $CI = 27$ –36, range = 21–48). Those females conceived at the average age of 29 months (95% $CI = 24$ –33, range = 18–45) assuming a 92-day gestation period.

Reproduction parameter estimates, including average birth interval length, average litter size, proportions of male and female nurslings, and parturition rate in the reference and treatment periods were similar (Table 11). The 95% confidence intervals on the differences of the estimates for each period for all parameters included zero.

Puma Hunters

The number of people requesting a permit to hunt on the UPSA each season in the treatment period ranged from 66–78 (Table 12). The number of hunters that responded to the voluntary surveys in the 5 seasons ranged from 40–62, representing 56–79% of the people that requested permits. Hunters did not answer all the questions on the survey, especially if they did not harvest a puma. The estimated number of active hunters on the UPSA each season ranged from 38–54. The greatest number of hunters participated in TY1. The lowest numbers of hunters were in TY4 and TY5 when the quota was reduced to 5 pumas. Hunters on the UPSA generally used dogs to hunt pumas, yet 1–4 individuals (median = 4) each winter said they did not use dogs. Forty-nine of 52 hunters indicated on their surveys that presence of marks (i.e., collar, eartags) would not influence their decision to harvest an animal. Two hunters indicated marks would make them more likely to harvest a puma; 1 killed a marked adult male and 1 killed a non-marked adult female. One hunter reported he would be less likely to harvest a marked puma; this hunter treed and released 2 different marked adult females and did not kill any others.

Harvest quotas on the UPSA during TY1–TY5 were reached by 11 December to 10 January each winter; the median date was 23 December. Only hunters using dogs harvested pumas. The number of days that hunters took to reach the 8-puma quota during TY1–TY3 ranged from 21–33 (Table 13). To reach the 5-puma quota in TY4 and TY5, it took 41 and 54 days, respectively. The number of days that each person hunted on UPSA ranged from 1–14, and the median number of days for each year was either 1 or 2. Hunter effort to harvest a puma ranged from 1–6 days and medians ranged from 1–2 days. During TY1–TY3, the number of days that hunters took to harvest a puma ranged from 1–4 (median = 1). It typically took the same number of days to harvest a male or female (median = 1), but the range was larger for males (1–4 days) than for females (1–2 days). During TY4 and TY5, the number of days to harvest a puma ranged from 1–6 (median = 1.5). The number of days hunted to harvest a female ranged from

Table 11. Puma reproduction parameter estimates and 95% confidence intervals in the reference and treatment periods, 2005–2014, Uncompahgre Plateau, Colorado, USA.

Reproduction parameter (units)	Period	Sample size	Estimates (95% CI)	95% CI on the difference ^a
Average birth interval (months)	Reference	17 intervals, 10 mothers	18.3 (15.5–21.1)	–3.1–5.4
	Treatment	13 intervals, 10 mothers	19.4 (16.2–22.6)	
Average litter size (cubs/litter)	Reference	26 litters, 14 mothers	2.8 (2.4–3.1)	–0.1–0.9
	Treatment	21 litters, 14 mothers	2.4 (2.0–2.8)	
Proportions of the sexes in litters (males, females)	Reference	41 male, 31 female	0.57 (0.45–0.69), 0.43 (0.31–0.55)	–0.023–0.301
	Treatment	27 male, 22 female	0.55 (0.40–0.69), 0.45 (0.31–0.60)	
	Both periods	68 male, 53 female	0.56 (0.47–0.65), 0.44 (0.35–0.53)	0.000–0.248
	Reference	12–13 adult females/year	0.63 (0.49–0.75)	
	Treatment	13–17 adult females/year	0.48 (0.37–0.59)	–0.12–1.32 ^b

^a We made inferences on period effects on these parameters by examining the 95% CIs on the differences of the estimates for each period using the delta method (Seber 1982). The 95% CIs on the differences for all tests included zero.

^b This 95% CI for the difference on the estimates is on the logit scale.

Table 12. Puma hunter participation during treatment year 1 (TY1) to treatment year 5 (TY5), 2009–2014, Uncompahgre Plateau Study Area (UPSA), Colorado, USA.

Treatment year ^a	Number of hunters that requested permit	Number of hunters that responded to survey	Percent of hunters that returned survey	Number of hunters that indicated they hunted on UPSA	Estimated number of hunters that hunted on UPSA
TY1	78	62	79	43	54
TY2	70	50	71	31	43
TY3	73	40	56	28	51
TY4	70	43	61	24	39
TY5	66	45	68	26	38

^a Puma hunting quotas on the UPSA included 8 pumas during TY1–TY3 and 5 pumas during TY4 and TY5.

Table 13. Lincoln-Petersen estimates (\hat{N}_c) of independent puma abundance and puma hunting and hunter survey results during treatment year 1 (TY1) to treatment year 5 (TY5), 2009–2014, Uncompahgre Plateau Study Area (UPSA), Colorado, USA.

Treatment year	\hat{N}_c	Harvest quota	Actual harvest	Number of days hunted on UPSA (range, median, <i>n</i>)	Number of days to fill the quota	Number of days per successful hunter to kill a puma (range, median)
TY1	57	8	9	1–14, 2, 51	26	1–4, 1
TY2	56	8	8	1–12, 2, 35	21	1–3, 1.5
TY3	44	8	8	1–6, 1, 31	33	1–3, 1
TY4	43	5	5	1–12, 2, 23	41	1–6, 1
TY5	37	5	5	1–5, 2, 32	54	1–5, 2

1–3 (median = 1), whereas days to harvest a male ranged from 1–6 (median = 2).

Hunters reported they encountered more fresh tracks (i.e., <1 day old) of females than of males during TY2, TY3, and TY5 (the survey in TY1 did not address this question), with annual male:female ratios ranging from 1:1.5–1:2.2 (Table 14). But in TY4, hunters reported they encountered more fresh tracks of males than females by a ratio of 1.8:1. The ratio of male to female tracks encountered by hunters in TY2, TY3, and TY5 reflected the observed male to female ratio of independent pumas in the population TY1–TY5, which annually ranged from 1:1.2–1:2.8. Our researchers encountered more fresh tracks of females than males each treatment year during our post-hunting capture operations, consistent with the sex structure of the independent pumas in the population after the seasons.

Hunters self-identified as selective 84–97% of the time and the sex ratio of independent pumas killed (2.2 males:1 female)

reflected selection toward males (Table 14). Hunters harvested more males than females, even though they reported encountering more fresh female tracks in 3 of 4 seasons that we asked this survey question. Hunters reported capturing and releasing 7 male and 19 female independent pumas during TY1–TY3. But in TY4 and TY5, hunters reported they caught and released 1 and 3 independent males, respectively, and 0 independent females.

DISCUSSION

Overarching Demographic Effects of Hunting

We found that annual harvest rates of independent pumas averaging 22% at the larger population scale and 15% at the UPSA scale over 4 years resulted in a 35% decline in their abundance on the main study area. As noted previously, however, the 15% UPSA-scale average harvest rate is biased low

Table 14. Counts arranged by sex ratio (male: female) of puma tracks recorded by hunters, pumas harvested, pumas captured and released by hunters, puma tracks recorded by researchers, and of independent pumas counted for Lincoln-Petersen (LP) estimates, and ratio of hunters that self-identified as selective:non-selective, treatment year 1 (TY1) to treatment year 5 (TY5), 2009–2014, Uncompahgre Plateau Study Area, Colorado, USA.

Treatment year	Sex ratio of first puma tracks <1 day old encountered by hunters ^a	Sex ratio of hunter-killed pumas	Sex ratio of pumas caught and released by hunters	Ratio of hunters that self-identified as selective: non-selective	Sex ratio of first puma tracks <1 day old encountered by researchers	Sex ratio of independent pumas counted for LP estimates pre-harvest	Sex ratio of independent pumas counted for LP estimates post-harvest
TY1	NA ^b	6:3	5:9	23:1	NA ^b	26:27	20:24
TY2	10:20	6:2	1:7	30:1	21:47	21:32	15:30

^a Tracks were assumed to be of independent pumas.

^b Not addressed in hunter survey in TY1.

because of the mis-match of the harvest limited on the UPSA (the numerator) relative to the number of independent pumas using this and adjacent areas (the denominator). Moreover, if we committed any errors by counting adults with failed radio-collars and others we back-aged to ≥ 2 years old in LP parameters, the actual UPSA-scale harvest rate would be higher. Hunting deaths were largely additive as indicated by a decline in survival and abundance and no reduction in other causes of mortality. Also hunting mortality was not fully compensated by reproduction and recruitment. Recruitment of young pumas did not compensate for losses of adult males and only partially ameliorated losses of adult females. The decline in puma abundance on the UPSA was likely due to the higher harvest rates occurring at the population scale, which included independent animals on the UPSA, those with home ranges overlapping the UPSA, and others on adjacent management units. We found that hunters exhibited selection for males, which reduced their survival and affected the sex and age structure of the population.

Change in Puma Abundance

Abundance of independent pumas changed on the UPSA as we manipulated hunting. Abundance increased with the absence of hunting on the UPSA and protection of marked pumas in adjacent management units. This occurred even with other natural and human causes of mortality acting on the animals. Thus, hunting mortality as it was applied prior to our study probably had reduced the abundance of pumas on the UPSA to a low phase and well below the capacity of the habitat. Moreover, the high finite growth rates of independent pumas on the UPSA, especially during RY4–RY5 and RY5–TY1 (i.e., $\lambda = 1.25$ and 1.39 , respectively), suggested that if the population continued to be protected from hunting, abundance would likely have increased further. Theoretically, had the non-hunted puma population been naturally limited by food and regulated by competition, growth would have declined (Logan 2019, Ruth et al. 2019). The decline, however, could follow a 4–8-year time lag (Laundré et al. 2007, Pierce et al. 2012). In our study, though, the absence and presence of hunting mortality determined population growth within the extents of the reference and treatment periods.

Our findings along with those from other western states reveal the range of puma population responses to variations in harvest rates (Fig. 12). At one end of the spectrum, a study in Utah revealed that abundance of independent pumas in the Monroe Mountains declined by $>50\%$ when subjected to an average 10% harvest rate (range = 7–12) over 6 years. That same population subsequently increased close to previous abundance when subject to an average harvest rate of 5% (range = 4–9) over 10 years (Wolfe et al. 2016). At the other extreme, pre-hunt estimates of independent pumas in a Wyoming population declined by 41% after 2 years with annual harvest rates of 43% and 44%. When harvest rates were reduced to an average 18% (range = 14–23), the population increased over the next 3 years to previous abundance by spring of the third year (Anderson and Lindzey 2005). The Wyoming study reports the highest known average harvest rate (i.e., 18%) associated with an increasing puma population. In this case, density-dependent population growth (*sensu* Logan and Sweanor 2001) might have regulated the rate of population recovery. In Washington, Beausoleil et al. (2016)

Figure 12. Average percent harvest rates of independent pumas associated with population trends in North America. Location designations refer to 2 harvest periods in 1 population in Utah (UT1 and UT2; Wolfe et al. 2016), a study in Washington (WA; Beausoleil et al. 2016), our Uncompahgre Plateau Study Area (UPSA) average harvest rate (COUPSA), our average population-scale harvest rate (COpop), and 2 harvest periods in 1 population in Wyoming (WY1 and WY2; Anderson and Lindzey 2005).

estimated puma density and found the population trend over 9 years to be stable or declining with an average annual harvest rate of 14% (range = 7–21) of independent pumas.

Caution is warranted in interpreting results from these cases, just as we noted biases with our own LP abundance estimates and the derived harvest rates on the UPSA. Potential biases in reported population sizes and harvest rates should be considered when minimum abundance indices are used (Wolfe et al. 2016) and abundance estimation methods require an assumption of population closure (Anderson and Lindzey 2005, Beausoleil et al. 2016) unless convincing evidence on geographic and demographic closure are provided to support the assumption. Moreover, reported variations in effects of hunting mortality on puma abundance may partly be due to differences in capacities for population growth (i.e., ecological carrying capacity; *sensu* Fryxell et al. 2014), other competing carnivores, regional population demographics, management actions at local and regional scales, parameter definitions, and population segment scales used in harvest rate estimation. Our study reveals how these latter 3 factors influenced estimated harvest rates.

Consistent with other research, we found that 21% of adult females in the total harvest at the population scale and 23% at the UPSA scale resulted in a decline in abundance of independent pumas that used the UPSA and surrounding area. The Wyoming puma population declined when adult females comprised about 25% of the harvest but sustained a harvest comprised of 10–15% adult females (Anderson and Lindzey 2005). Researchers in southern Idaho and northern Utah suggested that a harvest that included 15–20% adult females probably would not reduce a puma population (Laundré et al. 2007).

Mortality and Survival

In the absence of hunting on the UPSA, adult pumas died primarily of natural causes, especially intraspecific killing, and

human-caused deaths were rare. Deaths of subadults that occurred on the UPSA, by any cause, were unusual. Survival rates of adult and subadult males were high and exceeded those of their female counterparts. In contrast, regulated hunting in the treatment period reduced the survival of adults of both sexes and subadult males. Survival of independent males was substantially lower than of the independent females. Because of the ranging behavior of independent pumas, especially males, some were subject to hunting mortality on the UPSA and adjacent areas, which increased the risk of hunting mortality to those animals beyond the harvest limits set on the UPSA.

At the population sizes and harvest rates in our study, there was no compensation of hunting-caused mortality by a reduction in frequency of other causes of death for marked independent pumas in the treatment period. Natural mortality rates varied, and averaged about the same in the reference and treatment periods. But total mortality in the treatment period greatly increased over that in the reference period, primarily from hunting. Moreover, abundances of adult and independent pumas, and survival of adults and subadult males declined with the addition of hunting.

Hunting-caused deaths added to other mortality in other puma populations in North America. Researchers in Utah (Lindzey et al. 1992), Wyoming (Anderson and Lindzey 2005), and Montana (Robinson and DeSimone 2011) found that puma populations declined or increased as hunting mortality rates were increased or reduced, characteristics of additive mortality from hunting. Furthermore, researchers in Washington (Cooley et al. 2009b) and Montana (Robinson et al. 2014) directly addressed this issue and concluded that hunting mortality was additive at the puma population sizes and harvest rates they studied. In Utah, Wolfe et al. (2015) could not reject the additive mortality hypothesis of hunting for a heavily harvested puma population. They detected partial compensation of hunting mortality, however, associated with a decline in natural mortality in a lightly hunted population. To our knowledge the extent to which hunting mortality is additive or compensatory in puma populations that have reached or exceeded ecological carrying capacity has not been investigated. There may also be an extra-additive mortality effect (Creel and Rotella 2010) operating at increased rates of female harvest. When mothers with litters die, their cubs will also likely be lost (as in our study), which will reduce potential recruitment to the population.

Adult males on the UPSA were the most affected by hunting because of hunter selection. Within 4 years their annual survival and total winter abundance was reduced by more than half, including an almost halving in abundance of adult males <6 years old and likely elimination of males >6 years old. These demographic changes might alter the puma breeding process. Pumas have a polygamous and promiscuous mating system (Seidensticker et al. 1973, Anderson 1983, Logan and Sweanor 2010). Studies of non-hunted puma populations show that multiple territorial males compete for access to mates, and adult females choose mates from multiple available adult males and exhibit reproductive fidelity to males they chose in previous breeding occasions. Adult males in the same population exhibit highly variable individual reproductive success with a few adult males, especially the oldest, exhibiting the highest success

(Murphy 1998, Logan and Sweanor 2001). This process is expected to favor the fittest males (Darwin 1859, Andersson 1982, Jones and Ratterman 2009). Moreover, long-lived territorial adult males may establish tolerant if not amicable relationships (beyond breeding) with adult females residing in their territories that contribute to the fitness of the participating animals via higher survival of the adults and their offspring (Logan and Sweanor 2001, Ruth et al. 2011, Elbroch et al. 2017). Such a condition resulting in mating competition, mate selection, and social relationships likely occurred on the UPSA where after 5 years of no hunting, the abundance of adult males approached that of adult females and adult survival was high. Also, the long period of dependence for puma young reduces the operational sex ratio (i.e., the ratio of reproductively receptive males to receptive females; Clutton-Brock 2007), favoring adult males, and is to likely intensify mating competition (Logan and Sweanor 2001). In hunted puma populations with high adult male turnover, however, mating is expected to be constrained to relatively few available younger adult males with each male having low reproductive success (Logan and Sweanor 2010). For instance, in a Montana puma population reduced by hunting, 60% of litters were sired by males 30–37 months old (Onorato et al. 2011), and the oldest male was 6 years old (Robinson and DeSimone 2011). Thus, sexual selection processes may be relaxed (Mysterud 2011). This outcome was plausible on the UPSA when pumas were hunted, with all harvest occurring November to January and 92% of all litters sired afterwards, February through June. It is unknown if altering the breeding process through hunting-induced demographic changes affects the long-term fitness of pumas. To address this question, long-term research is needed on non-hunted and hunted puma populations where demographics, breeding behavior, survival, and individual reproductive success are studied (e.g., Milner et al. 2007, Newbolt et al. 2017, Bischof et al. 2018, Van de Kerk et al. 2019).

Growth in hunted puma populations has been shown to be most sensitive to adult female survival (Martorello and Beausoleil 2003, Lambert et al. 2006, Robinson et al. 2014). Empirical evidence on adult female survival rates and population growth in western North America reveal that puma populations have a greater tendency to decline when annual adult female survival is ≤ 0.78 (Fig. 13; Table 15). An exception is a puma population in competition with wolves and grizzly bears on the Greater Yellowstone Northern Range that declined with an adult female annual survival rate of 0.84 (Ruth et al. 2011, 2019). Puma populations have a greater tendency to increase when adult female annual survival rates are ≥ 0.86 .

Moreover, the risk of losing adult females to hunting is important because in any year females rearing dependent young may comprise a majority of the adult females in the population, a phenomenon in our study and in puma populations in New Mexico, Washington, and Montana (Logan and Sweanor 2001, Cooley et al. 2009a, Robinson et al. 2014, respectively). Adult females in our study were not affected as much by hunting as were adult males because of hunters' preferences to harvest males. Nevertheless, the survival of mothers while cubs were dependent was vital to cub survival. Similarly, in Montana, Robinson and DeSimone (2011) found that hunting influenced cub survival mainly owing to the deaths of mothers.

Figure 13. Adult female puma annual survival rates associated with population trends in North America. Location designations refer to Idaho and Utah (ID-UT1 and ID-UT2; Laundré et al. 2007), the Greater Yellowstone Northern Range before and during occupation by wolves (YBW and YDW, respectively; Ruth et al. 2011, 2019), Montana (MT1 and MT2; Robinson and DeSimone 2011), Washington low and high harvest (WAL and WAH, respectively; Cooley et al. 2009b), our reference period and treatment period (COR and COT, respectively), New Mexico (NM; Logan and Sweanor 2001), South Dakota (SD; Jansen 2011), Pacific Northwest (PNW; Lambert et al. 2006), and Utah low and high harvest (UTL and UTH, respectively; Stoner et al. 2006).

Cub survival estimates on the UPSA were generally lower than in 5 of 7 other western states, and was most similar to cub survival in the Greater Yellowstone Northern Range (Ruth et al. 2011; Table 15). In that population, which was lightly hunted and subject to competition with wolves and grizzly bears, Ruth et al. (2011) found that cub survival increased with elk calf biomass. We did not have data specific to the UPSA to test if cub survival varied with prey abundance. All starvation we observed in cubs occurred because their mothers were not alive to provision them. Cubs in a heavily hunted population in Washington had the lowest survival (Cooley et al. 2009b). Variation in reported cub survival estimates among the studies, however, may be affected by the ages of cubs included in the respective analyses. Inclusion of nurslings tends to result in lower survival estimates than data skewed toward older cubs because most mortality occurs in cubs ≤ 5 months old (this study, Logan and Sweanor 2001, Jansen 2011, Ruth et al. 2011).

Infanticide occurred at high frequencies on the UPSA in both periods. We observed that infanticide was primarily associated with males and tended to be higher in the reference period with an increasing abundance of adult males and lower in the treatment period with a declining abundance of adult males. Though, this did not lead to an increase in cub survival in the treatment period, likely because of concurrent increases in mortality of attending mothers. Ruth et al. (2011:1386) hypothesized “that instability of adult males, whether through removal (hunting or management related) or during re-establishment and population recovery, can result in increased [puma cub] mortality.” Presumably this would occur as adult

males compete for access to mates (Hrdy 1979, Logan and Sweanor 2010). The theory holds that periods of male territory instability reduce cub survival via increased infanticide as immigrant males and shifting adult males move into vacated territories and compete for mates (Logan and Sweanor 2001, Ruth et al. 2011). Our results indicated that infanticide certainly occurred in both conditions as hypothesized by Ruth et al. (2011), and contributed to relatively low cub survival on the UPSA. We could not test if infanticide rates declined with territorial stability, however, because adult male territoriality was unstable in the reference and treatment periods.

Reproduction

There were few differences in birth interval length, litter size, proportion of males and females in litters, and parturition rates between the reference and treatment periods. Thus, there was no evidence of a compensatory reproductive response associated with hunting mortality. Furthermore, there is no evidence that reproduction compensates for hunting mortality in pumas elsewhere in North America (Table 16). Data from our study, South Dakota (Jansen 2011), and Montana (Robinson et al. 2014) found litter sizes were similar in non-hunted and hunted conditions. Likewise, Cooley et al. (2009b) found that litter sizes did not differ in lightly hunted and heavily hunted study areas in Washington. Sex ratios of nurslings did not differ in non-hunted and hunted conditions on the UPSA. In South Dakota, males were favored in the non-hunted condition (Jansen 2011). The author of that study cautioned, however, that the results were likely an artifact of low sample size during a non-hunting period compared to the hunting period ($n = 6, 25$, respectively). Just as we found on the UPSA in the non-hunted and hunted conditions, researchers in New Mexico found similar parturition rates in a non-hunted area and where the number of adult pumas were experimentally reduced by half (Logan and Sweanor 2001). Both in Washington (Cooley et al. 2009b) and Montana (Robinson et al. 2014), mean maternity rates (i.e., kittens/adult female/yr) did not differ between lightly hunted and heavily hunted, or hunted and non-hunted populations, respectively.

The timing of observed puma births in North America may be influenced by weather conditions interacting with variations in prey abundance and distribution that affect cub survival. Cubs born during spring to fall are expected to have advantages for survival because of moderated weather conditions and increasing abundance and diversity of vulnerable prey (Laundré and Hernández 2007, Jansen and Jenks 2012). In contrast, cubs born in winter are expected to have lower survival and die as nurslings (Laundré and Hernández 2007). We could not test hypotheses about seasonal variation in cub survival, however, because we did not observe any births from October through February. Also as a practical matter, neonate deaths are expected to exacerbate the ability of researchers to detect such births (Logan and Sweanor 2001). Our observations of births on the UPSA primarily in early spring and summer (May–Aug) and peaking June to August were similar to birth distributions in South Dakota and Wyoming (Jansen and Jenks 2012, Elbroch et al. 2015, respectively). Puma births in Utah and Idaho (Laundré and Hernández 2007) and in Montana (Robinson and

DeSimone 2011) occurred almost year-round, but peaked July to October. In the Greater Yellowstone Northern Range, almost all births occurred from April to November with a major peak May to July and a second minor peak August to October (Ruth et al. 2019). In southern New Mexico, however, puma litters occurred almost year-round with a high frequency of births extending from May to October with a peak from July to September

(Logan and Sweanor 2001). Female pumas are polyestrous (i.e., cycle into reproductive receptivity continually until pregnant) and some mothers may lose entire litters at any time, which allows for some births to occur outside of the peak periods. Females can resume estrous within as few as 1–3 weeks and usually in 3–4 months after loss of a litter (Logan and Sweanor 2001, Ruth et al. 2019).

Recruitment

Puma population growth on the UPSA was affected by recruitment of young females and males from *in situ* reproduction and apparent immigration, and animals that emigrated. Offspring that exhibited philopatry as adults on the UPSA were infrequent, and mostly female. Dispersal of young from natal areas was frequent, with some of these animals settling as adults in other parts of the UPSA. Males emigrated more frequently and moved longer distances than females. Some pumas we captured as subadults with unknown origins were likely a combination of immigrants from elsewhere moving through or to the UPSA and non-marked offspring of mothers on the UPSA. We assumed some recruitment on the UPSA was from immigration because we observed subadults emigrating from the UPSA and expected other subadults were

moving into the UPSA. Recruitment in the reference period resulted in an increasing abundance of adults. In the treatment period, although there were more 1–2-year-old animals than in the reference period, recruitment was insufficient to replace losses of adults, particularly males, but it apparently partially compensated for adult female losses in 2 of 4 years (i.e., TY2 and TY4).

Philopatry and dispersal of young independent pumas have been reported by other researchers. Anderson et al. (1992) reported that pumas on the Uncompahgre Plateau in the 1980s displayed characteristics similar to our observations with philopatry exhibited by some females, although most females dispersed, and males dispersed more frequently and at longer distances than females. Investigators in New Mexico, the Northern Greater Yellowstone Ecosystem, and Utah reported

that philopatry was usually exhibited by females, that females and males dispersed, and males generally dispersed more frequently (Sweaner et al. 2000, Biek et al. 2006, Stoner et al. 2013, respectively). Longer dispersal distances were exhibited by males in New Mexico (Sweaner et al. 2000). But there were no sex differences in dispersal distances reported in Utah, the Northern Greater Yellowstone Ecosystem, and the Blackfoot drainage in Montana (Newby et al. 2013, Stoner et al. 2013). Philopatric males apparently occur more frequently in Southern California and Florida where puma habitat is fragmented by human development to the extent of obstructing or constricting dispersal movements (Beier et al. 1995, Maehr 1997, respectively). Dispersal by pumas, especially of males, is important in inbreeding avoidance and gene flow (Biek et al. 2006). Consequences of disrupted dispersal, as in pumas in California, include lower genetic diversity and strong population genetic structuring (Gustafson et al. 2019). Philopatry in males living in connected habitat appears to be exceptional, with 2 cases reported in the Greater Yellowstone Northern Range (Ruth et al. 2019), and possibly 2 that we found. High adult male mortality, as we documented in our study, and the associated reduced male competition might result in a higher frequency of young males expressing philopatry as an alternate strategy to dispersal, such as our 2 cases. Their deaths, though, from hunting at young ages might have precluded later dispersal.

The roles of emigration and immigration in puma population dynamics have been recognized in a number of regions in the western United States, including New Mexico, Utah, Washington, the Greater Yellowstone Northern Range, the Great Basin, and Montana (Sweaner et al. 2000, Stoner et al. 2006, Cooley et al. 2009a, Ruth et al. 2011, Andreassen et al. 2012, Robinson et al. 2014, respectively). These authors revealed that puma population segments interacted at a large landscape scale through immigration and emigration and recognized these as metapopulation processes (*sensu* Hastings and Harrison 1994) that along with *in situ* reproduction, mortality and recruitment determined population segment growth (Sweaner et al. 2000, Stoner et al. 2006, Cooley et al. 2009a, Newby et al. 2013). Our observations of pumas emigrating from the UPSA and their attendant long-distances moves to eastern Utah, northern New Mexico, and southern Wyoming indicated that pumas on the Uncompahgre Plateau are probably part of a larger metapopulation structure or one expansive contiguous population because of the connectedness of habitat in Colorado (McRae et al. 2005). In either case, local population segments or regions might exhibit varying growth rates influenced by the capacity of the environment and variable risks of mortality.

Associated with these dynamics, a source-sink model is recognized as biologically valid for depicting spatial variation of risk and inter-population connectivity for large carnivores including the puma (Sweaner et al. 2000, Laundré and Clark 2003, Cooley et al. 2009a, Ruth et al. 2011, Newby et al. 2013), black and grizzly bears (Draheim et al. 2016, Schwartz et al. 2010, respectively), wolf (Schmidt et al. 2017), and African lion (*Panthera leo*; Sinclair 1995). In a source-sink structure hunting mortality occurs in a spatially variable manner

and animals emigrate from protected or relatively lightly hunted source population areas (i.e., recruitment exceeds death rates and the area is a net exporter of individuals) and are immigrants into more heavily hunted areas that act as sinks (i.e., death rates exceed recruitment; Pulliam 1988, Hanski and Simberloff 1997, Runge et al. 2006, Stoner et al. 2013). Lower survival of pumas (Ruth et al. 2011), grizzly bears (Schwartz et al. 2010), African lions (Loveridge et al. 2010), and wolves (Schmidt et al. 2017) has been associated with movements of these animals from source areas to adjacent sink areas with higher human-caused mortality.

Population Structure

Hunting mortality changed the puma population structure on the UPSA. The first 3 years of the reference period, with no hunting, indicated a population with very few animals >6 years old, probably an effect of high hunting mortality prior to our study. With the continued absence of hunting, however, the age distribution increased as would be expected with greater survival of adults. After hunting resumed, the age distribution skewed younger, and abundance of adult males in particular declined, as expected with lower survival. Similar effects of hunting mortality or experimental removal on puma population age structure have been reported in New Mexico (Logan and Sweaner 2001), Wyoming (Anderson and Lindzey 2005), Utah (Stoner et al. 2006), Washington (Cooley et al. 2009b), and Montana (Robinson and DeSimone 2011).

The UPSA puma population in winter was structured similarly to other North America populations (Logan and Sweaner 2010). Adults represent multiple age cohorts and, thus, are the most abundant segment. Pumas have a polygynous, promiscuous mating system where adult females have smaller overlapping non-territorial home ranges compared to males and therefore generally outnumber adult males, which have large territories (Seidensticker et al. 1973, Logan and Sweaner 2001). Cubs are the second most abundant segment in winter, although they may be more abundant in the summer. This is because a large majority of mortalities occur when cubs are ≤ 5 months old and prior to their first winter (this study, Logan and Sweaner 2001, Jansen 2011, Ruth et al. 2011).

The subadult segment, representing a single cohort, was the least abundant in winter on the UPSA. Other researchers that quantified puma population structure in winter in New Mexico (Logan and Sweaner 2001), Utah and Idaho (Laundré et al. 2007), and Montana (Robinson and DeSimone 2011) also found that subadults were the least abundant life stage. Studies in Alberta, New Mexico, Montana, and South Dakota indicated pumas averaged 15–16 months old at dispersal (Ross and Jalkotzy 1992, Sweaner et al. 2000, Laundré and Hernández 2007, Robinson and DeSimone 2011, Jansen and Jenks 2012), similar to our observations. The average age of dispersal was 14 months in Wyoming (Anderson and Lindzey 2005). The low abundance of subadults we observed was probably partially due to mortalities that occurred in the cohort during the cub life stage, among subadults in the UPSA, and potential immigrating subadults outside the UPSA. For subadults, particularly males, mortality would be expected to be primarily from hunting (this study, Newby et al. 2013). Furthermore, most subadults would be

expected to emigrate from the UPSA before their first winter, as demonstrated by UPSA subadults we monitored, and before our winter efforts to survey puma abundance. Likewise, a large majority of young pumas in the Snowy Range of Wyoming emigrated between the months of April and September (Anderson and Lindzey 2005). In Utah, Stoner et al. (2013) reported that subadults emigrated primarily during March to June in association with heightened breeding behavior of adults.

Puma Hunters

Hunters on the UPSA normally used dogs to catch pumas, which usually took refuge in trees. This enabled hunters to assess the sex of a captured animal prior to deciding whether or not to kill it. Hunters were likely able to distinguish sex because of experience and sex identification material provided to them through the CPW puma education and identification course made mandatory since 2007 (CPW 2017). Similarly, experienced hunters using dogs in Washington were able to correctly identify the sex of treed pumas 70% of the time (Beausoleil and Warheit 2015).

Hunters selected for males even though they generally encountered fresh tracks of females more frequently than those of males, and females were more abundant. Our researchers' observations of more fresh tracks of females than of males were consistent with the hunters' reports. Hunters apparently encountered female tracks in relation to their relative abundance in the independent puma population. These results were contrary to the assumption that males as a group are more vulnerable to hunting with dogs because hunters detect tracks of males more frequently than those of females (*sensu* Anderson and Lindzey 2005). Instead, it is more likely that males are more vulnerable because of selection by hunters using dogs. Hunters in Washington killed more males than females when hunting with dogs but more females than males when dogs were subsequently prohibited (Martorello and Beausoleil 2003). The authors explained this shift occurred because hunters with dogs could practice selection, but when dogs were prohibited hunters encountered pumas by chance and killed the sexes relative to their abundance in the population. In Oregon, Clark et al. (2014a:785) found that hunting with dogs "greatly increased mortality of male [pumas] where male harvest was more than 2 times greater compared to when hunting with dogs was prohibited."

Hunter participation on the UPSA was highest when the harvest quota and puma abundance were high and lowest when the quota and abundance were low. Hunters used similar efforts to kill males and females when pumas were relatively abundant, but they took longer to kill males when the abundance of adult males was low probably because hunters still preferred to practice selection. Similarly, hunters took more days to reach the quota when the quota and abundance were lowest likely because of a reduced chance of encountering independent pumas, especially preferred adult males.

Hunter selection resulted in demographic effects that included substantially lower adult and subadult male survival and lower abundance and average age of independent males. Loss of adult territorial males may encourage the immigration of young males

as they search for puma habitat with high prey availability, prospective mates, and reduced male competition (Logan and Sweanor 2001, Laundré and Hernández 2003, Robinson et al. 2008).

MANAGEMENT IMPLICATIONS

Wildlife agencies can conserve and manage pumas by regulating hunting mortality. In our study, a harvest rate at the population scale averaging 22% of independent pumas over 4 years and with >20% adult females in the total harvest greatly reduced abundance. Puma abundance is the basic parameter that managers must consider either empirically, or theoretically in harvest management. Prevalent in their range, however, are non-surveyed regions where managers routinely extrapolate population parameter estimates derived from the literature. Density assumptions are commonly extrapolated, have questionable accuracy, and are used to calculate proxies for puma abundance estimates for the setting of harvest limits. Errors in assumptions can thwart achievement of management objectives. Results from our study and others in North America indicate that reducing puma abundance with hunting, particularly with the use of dogs, is fairly easy to achieve. But reliably managing puma population segments for conservation, while providing sustainable hunting opportunity, is more challenging. Thus, in non-surveyed areas managed for puma conservation and sustainable hunting, managers should apply conservative density assumptions and harvest rates to improve the odds of successful management. When resources allow for rigorous monitoring, puma abundance could be estimated over time using newly developed genetic sampling and photographic mark-recapture methods in representative management units (e.g., Proffitt et al. 2015, Beausoleil et al. 2016, Alldredge et al. 2019, Murphy et al. 2019).

Hunting is the only feature of puma mortality that managers can regulate to affect population size, as the other causes of mortality occur randomly and vary annually. Some non-hunting human causes of death (e.g., depredation control kills, some vehicle strikes) can be observed and quantified by managers, but natural deaths are rarely detected and some human-caused deaths (e.g., vehicle strikes, illegal killing) go unobserved. In addition, hunting deaths may not be compensated by increased survival, reproduction, and immigration (this study, Cooley et al. 2009a, Robinson et al. 2014, Wolfe et al. 2015). In areas managed for puma conservation and sustained hunting opportunity and where total human-caused mortality metrics are used to set mortality limits, all detected human-caused mortalities of independent pumas occurring year-round could be counted in those limits.

Regulated hunting used to manipulate abundance in smaller management units to address local issues (e.g., over-kill of adult females, depredation on livestock) may be successful if managers recognize the effects of hunting pumas in those areas and adjacent areas. We demonstrated this in the reference period by protecting marked independent pumas in adjacent northern management units for 5 years, which contributed to high survival and increased abundance of independent pumas on the UPSA. Conversely, abundance declined when all independent pumas were legal game in the UPSA and surrounding

management units. Moreover, emigrating pumas from the UPSA to areas across southwest Colorado, eastern Utah, and as far as southern Wyoming and northern New Mexico suggested that the UPSA plausibly could be receiving immigrants from just as far away. However, the emigration, dispersal distance, and establishment success of pumas could be negatively affected by human-caused mortality, particularly from heavy harvest (Newby et al. 2013). Therefore, larger regions for management purposes are more appropriate to the scale of puma movements and demographics. In our study system, that region ranged from about 11,600 km² to 12,300 km². The low range included the UPSA and 4 adjacent GMUs where marked pumas moved and prescribed our population scale. The higher range included the UPSA and all 5 adjacent GMUs where the management objectives were consistent (i.e., for a stable or increasing population state).

Results from our study revealed how the management outcome at the population scale can diverge from the stated objective and assumptions. To address this, managers could apply adaptive management (Walters 1986, Williams et al. 2001) to hunting and further learn its effects on puma behavior and populations. Besides informing puma management (e.g., Montana Fish, Wildlife, and Parks 2019), this process is also recommended for other harvested felids including African leopard (*P. pardus*; Balme et al. 2010) and Eurasian lynx (*Lynx lynx*; Linnell et al. 2010). In so doing, managers examine relationships of response variables (e.g., puma survival rates, ungulate survival rates, puma predation rates) to estimates of puma abundance or harvest data (e.g., Anderson and Lindzey 2005, Hurley et al. 2011, Wolfe et al. 2016), thus enabling them to apply the best available information and practices to puma management (Cougar Management Guidelines Working Group 2005, Jenks 2011).

Puma population dynamics in our study fit a source-sink management model, which can provide for conservation, hunting opportunity, options for mitigating conflicts with humans and other wildlife, and a framework for research (Logan and Sweanor 2001, Wyoming Game and Fish 2006, Robinson et al. 2008, Cooley et al. 2011, Robinson et al. 2014, Ruth et al. 2019). Similarly, a source-sink approach was developed for managing leopards in South Africa (Balme et al. 2010). Because managers rely upon assumptions about puma populations and effects of hunting in areas unless they are surveyed, they should consider the extents of areas managed with objectives for population reduction relative to those managed for stable or increasing abundance when puma conservation is a state-wide goal (Novaro et al. 2005). There are some likely protected (e.g., national parks and monuments, state parks) and lightly hunted areas already on the landscape. Managers need to reckon the validity of those as sources, however, by assessing the expected puma abundances within them, home range sizes, and movements in and around those areas and ascertain whether or not human-caused mortality along the perimeters might actually be creating sinks (Noss et al. 1996, Woodroffe and Ginsberg 1998).

Selective hunters using dogs and trained in sex identification of pumas could influence population demographics and facilitate source-sink management. Hunter selection can

reduce hunting pressure on independent females and contribute to sustainable puma hunting. Selection by hunters for males, particularly adults, can reduce independent male survival, reduce adult male abundance, and create a younger age structure. As puma abundance and the male component declines further, however, hunter selection and encounters with males are expected to diminish and result in higher adult female harvest (Anderson and Lindzey 2005), potentially with a reduction in survival of dependent cubs. Thus, protection of mothers and limits on adult female harvest are appropriate in areas managed for puma conservation and hunting. Similarly, in management plans where the roles of sex and age structure in life-history strategies are deemed important for adaptive potential, conservative harvest rates and pursuit-only opportunities could be applied in an effort to maintain a natural population structure. Dispersal of non-selected pumas from those areas and refuges from harvest and into more heavily hunted areas with attendant recruitment and genetic mixing could counteract potential effects of selective harvest (Tenhumberg et al. 2004, Festa-Bianchet 2017). Conversely, hunters with dogs are capable of efficiently harvesting pumas and causing population declines in areas where that is a management objective.

ACKNOWLEDGMENTS

We dedicate this work to Allen E. Anderson, the first biologist to study pumas on the Uncompahgre Plateau, and John M. Kane, our first houndsman on this project. This work was accomplished because of devoted, skilled field people, including our other houndsmen: W. Hollerman, W. C. Jesson, V. E. Johnson, J. M. Knight, J. L. McNamara, R. J. Navarette, B. A. Nay, A. M. Robinson, H. J. Taylor, W. W. Wilson, and S. M. Young. Likewise, we are indebted to our biologists: R. S. Alonso, C. B. Anton, S. M. Bard, J. W. Bauer, B. L. Bavin, A. C. Burnett, A. R. Butler, B. K. Dunne, A. R. Greenleaf, C. E. Jacobs, J. Mannas, G. J. Merrill, T. Murphy, E. C. Phillips, D. H. Ranglack, Y. N. Shakeri, B. D. Simpson, J. M. Timmer, D. E. Unger, J. E. Waddell, E. M. Wampole, and V. Yovovich. We thank S. D. Waters for his skilled piloting. L. L. Sweanor assisted with capturing and monitoring pumas. D. M. Bresett and D. C. Trainor administered the hunter permits and surveys. M. M. Flenner and K. J. Aagaard conducted the GIS analyses and produced the maps. Funding was mainly from hunter fees in Colorado and Federal Aid to Wildlife Restoration Project W-244-R. Additional support was granted by the Howard G. Buffett Foundation, Safari Club International Foundation, and The Summerlee Foundation. We are grateful for cooperation from private landowners, the Bureau of Land Management, Ridgway State Park, United States Bureau of Reclamation, United States Department of Agriculture (USDA), Animal and Plant Health Inspection Service Wildlife Services, and USDA Forest Service. We thank M. W. Alldredge, C. R. Anderson, M. Ben-David, E. J. Bergman, J. S. Lewis, D. P. Onorato, L. L. Sweanor, M. E. P. Vieira, and 2 anonymous reviewers for constructive comments that improved this manuscript. C. Lopez Gonzalez and G. Bastille-Rousseau wrote the Spanish and French abstracts, respectively.

POPULATION MANAGEMENT OF BEARS IN NORTH AMERICA¹

STERLING D. MILLER, Alaska Department of Fish and Game, 333 Raspberry Rd., Anchorage, AK 99518-1599

Abstract. Population management for black bears (*Ursus americanus*), brown grizzly bears (*U. arctos*), and polar bears (*U. maritimus*) in North America is reviewed. In different areas bear populations are managed to achieve goals of population control, conservation, or sustained yield. Most North American bears are managed for sustained yields and this topic is emphasized. The consequence of error in population management for US bears is to produce slowly and reduced populations will require many years to recover. Simulation results where reproductive rates were generous, natural mortality rates were low, and harvests were 15% of maximum sustainable rates, indicated that populations reduced by half will require 140 years to recover for brown/grizzly bears and 117 years for black bears. Under optimal conditions for reproduction, natural mortality, and with males were as vulnerable as females, maximum sustainable harvest mortality was estimated as 5.2% of total population for grizzly bears and 14.2% for black bears. In recent decades, all 3 species have obtained the status of game animals in most jurisdictions and management for control objectives is increasingly uncommon. Management for conservation requires primary emphasis on habitat protection and on minimizing mortality from any source. Managers of hunted bear populations use information from hunters, trappers, and age composition of killed bears from research programs, and from computer simulation studies. Some critical uses of data from any of these sources may lead to management error. Data on age at harvest is especially prone to misinterpretation. Techniques used to limit harvests by managers of hunted bear populations are reviewed. The primary constraints to long bear population management derive from inadequate habitat protection, political pressures, technology, a limitation of available population management techniques, and inadequate financial support for management.

Int. Conf. Bear Res. and Manage., 9:357-373

Population management efforts designed to enhance or stabilize bear numbers are recent in the United States and Canada. In the last century and early portion of the present century, black and grizzly bears were widely regarded as impediments to desired development and human safety. Bounties for killing bears were offered in many jurisdictions. This attitude, combined with habitat destruction, led to the elimination of grizzly bears throughout most of the United States except Alaska and the reduction of black bears especially in the southern and southeastern United States (Cowan 1972, Jonkel 1987). By the mid-19th century, polar bear populations were also greatly reduced by market hunting for their hides (Anon. 1965, Stirling 1986).

Attitudes towards bears began to change in the 20th century. Instead of being classified as "predators" or "vermin" that could be killed indiscriminately, bears were classified as fur animals subject to regulated commercial harvests. By the 1930's, bears were elevated to the status of "game" animals in most areas (Table 1). Typically, limitations on sale of hides, meat or other bear products came along with game animal status as well as significant limitations on hunting opportunities (seasons, bag limits, techniques, etc.). In some areas further limitations resulted when bear populations were greatly depleted. At this point populations were classified as "threatened", the status of the grizzly in the lower 48 states, or "endangered", such as the black bears in Texas since 1987 (Wallace 1987). There is nothing inevitable about a downward trend in bear numbers to a threatened or endangered status. For black bears, at least, popula-

tions currently are stable in much of the United States and Canada. Also, in some regions, with formerly depleted populations of all 3 species, bears have recovered to a secure status.

The techniques used in modern bear management are the subject of this paper. These techniques are applied to 3 general goals for population management listed by Caughley (1977:168): *control* (treatment of a population that is too dense to stabilize or reduce its density), *conservation* (treatment of a small or declining population in such a way as to raise its density), and *sustained yield* (exploitation to take from a population a long-term sustained yield of surplus animals without causing a population decline). Although all 3 of these goals are discussed, primary emphasis in this paper is on sustained yield management.

This paper was prepared in response to an invitation from E. Bunnell to prepare a plenary paper for this conference. Numerous persons very kindly responded to my request for management plans and other information that described how bears are managed in their jurisdictions including: S. Amstrup (AK), R. Archibald (BC), J. Beecham (ID), L. Berchault (NY), J. Brown (MT), J. Collins (NC), A. Doud (MT), K. Elowe (MA), D. Garshelis (MN), J. Gunnson (AB), R. Johnson (WA), D. Koch (CA), G. Kolenosky (ON), O. Oedekeoven (WY), A. LeCointe (AZ), D. Martin (VA), R. Masters (OK), C. McLaughlin (MA), E. Orff (NH), J. Pederson (UT), A. Polenz (OR), J. Rieffenberger (WV), S. Schliebe (AK), J. Schauf (KY), C. Servheen (MT), B. Smith (YK), J. Stahl (MI), D. Taylor (AK), M. Taylor (NW), C. Winkler (TX), and J. Wooding (FL). K. Schneider, C. Schwartz, S. Stringham, and 3 anonymous referees offered many valuable suggestions on an earlier draft of this manu-

Table 1. Year in which bears were declared to be game animals at different portions of North America. Dates refer to black bears except where indicated by "G" for grizzly bear or "P" for polar bear.

¹ Date of first bag limit or season restriction.

² First declared game in 1924, replaced, then redeclared in 1970.

³ Viller (1977) cites 1970 as date game status was assigned in Quebec.

⁴ Date of total season closure.

⁵ Harris and Huger (1977) state black bears were hunted until 1951 and game status was being recommended in 1977.

⁶ Date of first season game animal status repealed in 1951 in some areas, reinstated in 1969.

⁷ Bunker (1973) gives 1957 as date game status was assigned in California.

⁸ Date of legal basis for current management.

⁹ Polar bears in Ontario have been treated, for management purposes, as a furbearer since 1931 (cf. Kalnitsky, Dist. Ministry of Nat. Resour., Maple, pers. commun.).

¹⁰ 520 hours followed from 1955, first season in 1961.

script. The work was funded by Federal Aid in Wildlife Restoration Project W-22-6, Job 4.18R and the Alaska Department of Fish and Game.

CONSEQUENCE OF ERROR

For all 3 management objectives the consequence of error in managing bear populations is high. Bear populations that are inadvertently reduced to lower levels than desired will require many years to recover. This is because all 3 species of North American bears have long lifespans (>20 years), low reproductive rates (an average of 2 cubs produced by adult females every 2-6 years), delayed reproductive maturity (first breeding at 3-7 years), high survivorship of adults, variable survivorship of young, which is frequently dependent on environmental conditions (Rogers 1983), and typically little fluctuation in number of adults from year to year (Junkel 1987, Kolenosky and Strathern 1987, Kolenosky 1987).

The period required for recovery of reduced populations of black and grizzly bears was simulated using a simple deterministic model (Miller and Miller 1988) in a scenario involving overharvests by hunters. In these simulations, maximally productive populations of black and grizzly bears that were stabilized by hunting were suddenly overharvested by doubling the exploitation rate. When the population declined to half its original size, hunting was restricted and the time required for the population to recover to its initial size was noted. When no hunting occurred during the recovery period, the black bear population recovered in 6 years compared to 10 years for grizzly bears (Table 2). When hunting during the recovery period occurred at 75% of the maximum sustainable hunting rate, it took almost 3 times longer for black bears to recover and 4 times longer for grizzly bears (Table 2). These results are minimal values as the reproductive and natural mortality rates used were set at the most optimistic values that have been reported (Miller 1989).

Table 2. Simulation results for estimating period required to recover from overhunting that caused a 50% reduction in maximally productive grizzly bear and black bear populations. During recovery period population was subject to hunting rates of 0, 50, and 75% of the initial rates at which populations were stable.

	Grizzly bear	Black bear
Years required to recover from reduction when hunting is held at following fractions of initial hunting rate		
No hunting	10	6
50%	19	9
75%	40	17

MANAGEMENT FOR CONTROL OF BEAR NUMBERS

Until the current century, reduction of bear numbers was the most common objective for bear population management. In some parts of North America, bears are still sufficiently abundant or troublesome to humans that management efforts involve reducing bear densities (e.g., Poelker and Hartwell 1973, Jorgensen et al. 1978, Ambrose and Sanders 1978, Poelker and Parsons 1980, Will 1980, Miller 1990a, Gasaway in press). Such areas have become increasingly rare and geographically restricted in recent decades. They will likely become even rarer.

However, where human and bear populations coexist, managers will have to deal with some problems. These problems can result in bear mortalities that are large enough to be significant from a population management standpoint. For Yellowstone grizzlies, control killings of only a few additional females may mean the difference between continued population decline and recovery (Knight and Eberhardt 1984, 1985). In such cases, human populations, not bear populations, must make the needed accommodations for coexistence.

Many states and provinces compile data on the number of human-bear conflicts reported. It is sometimes implied that an increase in the number of nuisance bear complaints reflects an increase in bear numbers. More often, however, increased complaints reflect a change in human use of bear habitat. Increased human-bear conflicts more commonly correspond to a decline in bear populations, not an increase.

Research in Alaska and other northern regions has demonstrated that predation from bears and wolves (*Canis lupus*) can inhibit recovery of depleted moose (*Alces alces*) and caribou (*Rangifer tarandus*) populations (Ballard et al. 1980, Franzmann et al. 1980, Gasaway et al. 1983, Ballard and Larsen 1987, Ballard and Miller 1987, Boertje et al. 1988). These findings have resulted in pressure from sportsmen and subsistence hunters to reduce numbers of predators to permit faster growth and higher harvests of prey populations. In response to such pressures, grizzly bear seasons have been liberalized and harvests have increased in many portions of interior Alaska (Miller 1989). These changes represent a geographically widespread shift from conservative grizzly bear management strategies to more aggressive ones in which the likelihood of management error in these areas is increased. In at least 2 areas, increased harvests have resulted in declines in grizzly bear populations (Reynolds and Hechtel 1988, Miller 1990a). Elsewhere, results are inconclusive (Gasaway 1988) or no field studies designed to evaluate trends in bear numbers are ongoing.

Responsible management of bear populations under circumstances such as these is especially challenging because the techniques available to document changes in bear populations are imprecise. This makes it difficult to establish realistic criteria by which to judge when bear population reduction goals have been met. Also, there sometimes is inadequate recognition that management prescriptions for predator reduction programs that involve bears (e.g., Gasaway in press) need to be different than for predators like wolves that have much higher reproductive rates.

MANAGEMENT FOR CONSERVATION

Conservation is the general objective for grizzly bear management efforts in the lower 48 states, for black bear management in southern and southeastern states, and for management of all species in national parks. In some large Alaskan parks where grizzly bears are abundant, population management is less important than people management and habitat protection. Most national parks in the U.S. and Canada are not so fortunate and require active bear management to assure perpetuation of bear populations (Knight and Eberhardt 1987, Knight et al. 1988, Horejs 1989).

Even in parks and other protected areas, baseline data on population density and composition may be critically important in evaluating impacts of environmental accidents or changing patterns of human use of areas occupied by bears. The absence of a systematically obtained baseline estimate of bear density in Katmai National Park made it difficult to evaluate whether the bear population had declined as a result of the 1989 oil spill from the *Exxon Valdez*. Similarly, in Glacier National Park, the lack of a systematically collected historical record of bear numbers made it difficult to isolate human use patterns, which may have caused a reduction in bear numbers (Hayward 1989, Keating 1989).

In parts of North America small bear populations survive only in small pockets of habitat isolated from each other. This fragmentation exposes these populations to higher probabilities of extinction because of chance events and environmental variation. Managers of these populations must determine how large these populations and reserves should be to insure persistence in the face of natural catastrophes, and random environmental, demographic, and genetic events (Schaffer and Sampson 1985). For Yellowstone grizzlies the minimum viable population that gave a 95% probability of surviving for 100 years was estimated at 50-90 bears (Schaffer and Sampson 1985). Using the same general approach but with different data on mortality rates, the estimated

minimum viable population was estimated at 125 bears (Suchy et al. 1985).

The Interagency Grizzly Bear Committee formed in 1983 is an example of the kind of coordination that is essential if remnant populations of grizzly bears are to survive in the lower 48 states (Salwasser et al. 1987). This committee includes representatives of 5 U.S. agencies that manage portions of grizzly habitat plus 6 state or provincial wildlife agencies, and 2 Indian tribes. Working together, these agencies have developed a coordinated set of objectives and strategies to direct conservation efforts. The International Agreement on the Conservation of Polar Bears and their Habitat is another example of the kind of cooperation needed to perpetuate healthy bear populations (Stirling 1986, 1988a).

Techniques for estimating population size and trend, discussed below, are especially needed in management of reduced populations for conservation objectives. Unfortunately, some of the techniques that provide the most accurate population estimates may frequently be inappropriate for very small remnant populations of bears because these techniques are usually imprecise when applied to small populations. In addition, subjecting such populations to the additional stress and mortality associated with marking studies may be unwise. In managing greatly reduced remnant populations of bears, managers may find it more productive to concentrate on habitat protection issues rather than on efforts to document bear numbers or mortality rates with marking studies that may produce only uncertain results.

SUSTAINED YIELD

Sustained yield management of bear populations is the management goal in most areas of North America inhabited by bears. Most commonly the yields are taken by hunters. Perhaps because sustained yield management is not usually conducted in a crisis atmosphere where bear populations are threatened or where bears are seen as damaging to humans' economic interests, sustained yield management has not received as much attention as it deserves. More concern is merited because correct management of populations that have sustained yield goals may prevent crisis situations from developing. Also, population management techniques are especially important in managing for sustained yields. For these reasons this topic is given primary emphasis in this review.

The principle behind sustained yield management is that populations produce a surplus of animals that can be removed or harvested without causing population declines. Under sustained yield management, harvesting

takes the place of mortalities that would occur from old age and other causes. In very dense populations, reproductive rates of bears are suppressed by density-dependent mechanisms that act to prevent the population from overshooting carrying capacity. Because population growth is suppressed by these mechanisms, populations at carrying capacity can support little harvest. If such dense populations are harvested and bear density declines, reproductive rates should increase and natural mortality rates should decline, which produces a surplus that can be taken annually without causing declines in bear numbers. Maximum sustainable yield (MSY) is the point where population size and productivity balance to produce the maximum size of harvest without causing a population decline. At populations lower than MSY, productivity and sustainable harvest rates remain high but fewer total bears can be harvested without causing a population decline.

For bear managers the MSY population size is more useful theoretically than practically since the "optimum" population size will be unknown. This is because reproductive and mortality rates can vary from year to year in a density independent fashion based on fluctuations in food supply (Jonkel and Cowan 1971; Rogers 1976, 1983, 1987). Managers striving for sustained yields from exploited bear populations try to maintain populations that have good average reproductive rates and small average natural mortality rates in the expectation that such populations will be producing harvestable surpluses at high levels.

The challenge facing managers managing bear populations for sustained high harvests is to identify correctly what harvest levels are sustainable and when sustainable levels are exceeded. To assist in making these determinations the population manager may have information available from hunters, from the animals that are harvested, from field investigations, and from simulation studies.

Information Provided by Hunters

Hunters can provide valuable information to managers of exploited bear populations. Information from hunters is most useful as a flag that alerts managers to potential problems or helps to form hypotheses about population status. These hypotheses can then be evaluated using other lines of evidence.

Number Killed. -- Perhaps the single most basic and useful piece of information that can be provided by hunters is the number of bears killed. Increasing numbers of bears killed should alert managers that populations could be declining. Of course, population trend is not

necessarily correlated with number killed; increasing harvests could occur without population decline as long as sustainable harvest levels were not exceeded.

Probably the best way to use data on harvest number requires calculation of sustainable harvest rate. With information on reproductive and mortality rates derived from research, this rate can be estimated using simulation models, discussed below. The calculated sustainable rate can be compared with actual harvest rate obtained by dividing number killed by estimated population size. This approach resulted in a recommendation against an increase in polar bear hunting quotas in the Northwest Territories (Stirling et al. 1985).

In a few instances, efforts have been made to use kill numbers to derive population size by assuming the kill represents some percentage of the total population, usually the calculated sustainable harvest rate, and back-calculating from this rate to derive a total population estimate. This is a reasonable procedure only if managers have independent evidence that the population is stable.

Unreported sport or nuisance kills and wounding losses can represent significant sources of mortality that managers should consider. In rural northwestern Alaska, less than half the grizzly bear sport and subsistence harvest is reported as required (W. Ballard, Alas. Dep. of Fish and Game, Nome, pers. commun.). On the heavily hunted Kenai Peninsula in Alaska, where reporting is thought to be fairly complete, wounding loss of black bears was estimated to be 13-16% of reported kill based on mortalities of radio-marked bears (Schwartz and Franzmann in prep.). "Control kills" of nuisance black bears accounted for 36% of known human-caused mortalities and unreported control kills were estimated to equal or exceed reported ones in the Yukon (MacHutchon and Smith 1988). Poaching accounted for 9% of deaths of marked black bears in Maine (Hughie 1982). A third of the known grizzly bear mortality was illegal harvest in Alberta (Peck et al. 1987). The mortality rate of marked grizzlies in Montana was estimated at 0.47, all from illegal, unreported kills (Knick and Kasworm 1989). In 6 studies of marked grizzly bears, 26% of mortalities were caused by illegal harvests compared to 42% by legal hunting (McLellan 1990). Managers need to incorporate estimates of all significant mortality sources into their bear management efforts.

Hunter Effort. -- Number of bears killed is best interpreted along with information on level of hunting effort. Increases in number of bears killed under conditions where effort is constant may lead managers to suspect an increasing bear population. The same increase in harvest number where effort is also increasing may suggest an

increased exploitation rate and a declining bear population. This indicator was used in Alberta, where managers noted that harvests of grizzly bears increased 140% during a period when effort increased 350% (Nagy and Gunson 1988). In a heavily hunted area in south-central Alaska where grizzly bear density was reduced by about half as a consequence of liberalized hunting regulations, successful hunters reported spending more time before shooting a bear than before the density was reduced (Miller 1990a). Typically, hunter effort data are highly variable and statistical tests seldom reveal significant differences. This does not, however, invalidate the cautious use of such effort data to assist managers in forming hypotheses about population trends.

Hunter Success. Hunter success rates are influenced by improved access or hunter technology, motivation, and number of bears. This means that effort indices should be used with caution. Variability in effort unrelated to population status is apparent in Alaska where non-resident grizzly bear hunters are required to hunt with guides and pay high fees. Resident hunters have no such restriction and need only buy a \$25 tag. These differences in cost of hunt affects motivation and is reflected in success rates. The statewide success rate for non-residents is much higher (52% in 1987) than for residents (8.4%) (Alaska Dep. of Fish and Game [ADF&G] unpublished file data). However, in the Game Management Unit that includes Kodiak Island, where highly prized brown bear hunting permits are allocated by lottery, both types of hunters had higher success rates: 19% for residents and 74% for non-residents (ADF&G unpublished file data for 1986). In contrast, average harvest success rate for grizzly bear hunters in Alberta was 3% for residents and 12% for non-residents during 1971-1987 (Nagy and Gunson 1988). Even where hunting is limited by permits, hunter success can be low. Arkansas black bear permittees had 0.4-2.2% success in different years (Pharris and Clark 1987). This variability underscores the need to look for trends in success rates within groups that are as homogeneous as possible with respect to residency, transportation type, motive, and area hunted.

Kill density. The geographic location of hunter kills is also important. Harvest number with geographic location permits managers to estimate kill per unit area or kill density. Excluding effects of immigration, sustainable kill density can either be calculated (like sustainable harvest numbers) or estimated based on areas where both population trend and kill density are known. Kill density divided by population density was used to approximate grizzly bear harvest rate in a heavily hunted portion of

Alaska (Miller 1988, 1990a). Kill density estimates were used to illustrate that dangers of overkill of a grizzly bear population was higher in the Canadian portion of the Northern Continental Divide Ecosystem where a legal hunting season was in place than on the U.S. side (Horejs 1989). Kill density also can be used to establish quantifiable management objectives in management plans.

Integrated Approaches. In Minnesota, black bear population managers use a hunter survey to collect data on hunting success and bears killed per hunter-day. Data are adjusted to correct for annual variation in food abundance and are used to select the most conservative growth curve that fits this trend from a series of model-generated curves of population growth. Managers then use the selected curve and some subjective criteria to develop estimates of population size and to set harvest quotas (D. Garshelis, Minn. Dep. of Nat. Resour., Grand Rapids, pers. commun.). This approach appears to be a worthwhile effort toward integrating information obtained from hunters with that from other sources into a standardized management framework useful in making objective management decisions.

Information Provided by Harvest Composition

Detection of bear population trend from the sex and/or age structure of harvested bears is more often attempted than achieved (Caughley 1974, Wiley 1980, Gilbert et al. 1978, Bunnell and Tair 1980, 1981, Miller and Miller 1988). Procedures that are appropriate for more productive ungulate populations (e.g., Fraser 1976, Fryxell et al. 1988) are difficult to apply to bears because they are a long-lived and low density species that can sustain only low harvest rates (Harris and Metzgar 1987a). Low harvest rates provide a small sample of harvested animals from which to make inferences about the population and a delay in the time required for harvest to perturb the population's sex and age structure. Sex ratio of harvest is more sensitive as an indicator of population status than age structure (Harris 1984), perhaps because all the harvest is distributed between only 2 sexes compared to 20 or more age classes. It is popular to try to use data on age composition of harvest because hunters can be required to submit teeth from their kills. These can be sectioned and age estimated by counting cementum annuli (Stoneberg and Jonkel 1966). The age of harvest results in tables of supposedly "hard" data, the utility of which is more frequently assumed than demonstrated.

Differences in the sex and age composition of bear populations subjected to different levels of hunting have been documented (Jonkel and Cowan 1971, Beecham 1980, Kolenosky 1986, Reynolds and Hechtel 1988,

Miller 1988, 1990a). As yet, these differences have not been clearly related to differences in the age composition of bears harvested from these populations. Increases in number of black bear females harvested has been correlated with increased harvest rate in Ontario (Kolenosky 1986).

The sample of bears shot by hunters will seldom directly reflect the population composition. Hunters are selective and bears have differential vulnerability based on sex, age, or reproductive status (Bunnell and Tait 1980). A further problem is that most interpretations of harvest composition data assume a stable age distribution, which is usually inappropriate. Relaxation of stable age distribution assumptions may be possible if independent information on rate of change in population is available (Giberhardt 1985, 1988).

Commonly, age data on sex or age composition of bear harvests are used to infer that populations are stable because mean (or median) age or sex ratio of harvested animals is constant. Similarly, some managers look for decreasing mean (or median) age of harvest (especially of males) or increasing proportions of females in the kill as indicators of overharvest. Such interpretations can lead managers into unwarranted complacency about population status. When birth and death rates are constant, the sex and age composition of the population will stabilize regardless of population trend. This has been recognized since the 1907 paper by Lotka (Caughley 1977) but remains a source of confusion. When birth and death rates are not constant or vulnerability by sex or age class is changing, harvest composition may change in response. This change, however, is not necessarily related to a change in population status.

Managers should be cautious in setting planning objectives based on age or sex ratio in harvest statistics. Benchmarks such as "no fewer than 60% males in the total harvest" may be inadequate to prevent overexploitation. The sex ratio of harvest at sustainable harvest levels is not a constant. Instead, this value is a function of a number of factors including the relative vulnerability of each sex to human-caused mortality, sex and age-specific natural mortality rates, proportion of total mortality that is represented by harvest, and sex ratio at age of first vulnerability to hunters. Failure to meet an objective of at least 60% males could, for example, be "remedied" by adding an early spring season when males have high vulnerability (O'Pezio et al. 1983, Miller 1990b, Van Daele et al. 1990) rather than by decreasing kill of females. It is preferable to set exploitation guidelines in terms of the total adult female harvest as has been done for polar bears (Taylor et al. 1987b).

A promising approach to interpretation of sex and age composition of black bear harvest data was suggested by Fraser et al. (1982). This approach exploits the higher harvest vulnerability of males compared to females (Bunnell and Tait 1980), which results in a progressive decline in the proportion of males in older age classes. At some age, the higher vulnerability of males will be offset by the larger number of surviving females and the harvest at that age and older will favor females. In lightly exploited populations the age at which females predominate in the harvest will be older than in heavily exploited populations. A regression of percent males in harvest on age class will have a steeper negative slope in heavily hunted populations (Fraser et al. 1982).

Simulation studies have indicated that for bears this model is sensitive to a number of likely violations of underlying assumptions (Harris and Metzgar 1987a). Even if it lacks robustness, however, this approach may be useful as a tool to examine conflicting interpretations of available data. In a portion of south-central Alaska, the Fraser et al. (1982) approach was successfully used to document that current grizzly bear exploitation rate was higher than formerly (Miller 1988). Even though harvest rate could not be directly estimated because of violations of the model's assumptions, this analysis was useful in discrediting the hypothesis that the bear population was unaffected by increased harvests. Also, the most likely bias in the use of the Fraser et al. (1982) approach in Alaska would have resulted in an underestimation of harvest rate. This was because vulnerability of females declined in the adult age classes when females were periodically protected by being accompanied by offspring (it is illegal to shoot grizzly bears accompanied by cubs or yearling offspring). Because the estimated harvest rate was an overestimate but was still higher than the calculated sustainable rate, it was useful in demonstrating a clear need for reduced harvests.

A more complex approach for interpreting sex and age composition of harvest data was developed by Tait (1983). Using sex and age composition of harvest data, Tait's approach uses non-linear optimization procedures to develop maximum likelihood estimates for historic population size, hunting rate, recruitment rate, and other parameters. Unfortunately, Tait's model has yet to be adequately tested with real harvest data or evaluated to see how robust it is when underlying assumptions are violated. Alaska is currently making an effort to conduct such tests.

The limitations of sex and age composition of harvest data should not discourage managers from collecting these data and continuing to investigate meaningful ways

of using them. Compared to field studies as a way of evaluating population status, harvest data are much less expensive to collect. In using these data, managers must be aware of the limitations, however, as common misinterpretations could lead managers into misclassifying declining populations as stable. With existing technology, it is clear that the limitations on use of composition of bear harvest data are such that hunting remnant populations of bears cannot be justified on the basis that such data would be helpful in evaluating population status.

Information Obtained from Research

Research is an important component of sustained yield management for bears. Research is necessary because bear population management has few generally accepted techniques that can be widely applied to evaluate population size or trend (Harris 1986). Research is not needed for each exploited population. Frequently, adequate results can be obtained by cautious extrapolation from research done elsewhere. However, it should be recognized that responsible sustained yield management of a bear population will be expensive and may require field studies to estimate population size, population density, movements, or critical reproductive and mortality rates.

Population Size and Trend. Research programs most commonly address estimation of population size. Frequently, population size is estimated using some variation of capture-mark-recapture procedures such as the Seber-Jolly technique (DeMaster et al. 1980, Beecham 1983, Amsnip et al. 1986, Kolenosky 1986). This technique requires an estimate of survival rate in addition to the other standard assumptions of capture-recapture procedures (Seber 1982). Where survival estimates are not available, black bear population estimates have been obtained using more traditional Lincoln Index procedures (Jonkel and Cowan 1971, LeCount 1982, Young and Ruff 1982, Miller and Ballard 1982, Beecham 1983, Aune and Brannon 1987). Frequently it is difficult to convert population estimates obtained using such techniques to density estimates because of uncertainty about size of the area occupied by the estimated population.

In Alaska, intensive capture-recapture techniques using radio-telemetry to correct for lack of population closure have been used to derive black and grizzly bear density estimates in small ($<2,000 \text{ km}^2$) areas (Miller et al. 1987). With this approach the area occupied by the estimated population does not have to be estimated. In 1 area this technique was used to document statistically significant declines in bear numbers caused by hunting (Miller 1990a). Elsewhere, these estimates serve as baselines for

documenting potential changes in density caused by hunting, development, or habitat deterioration (Schoen and Beier 1989, Miller and Sellers 1989, Ballard et al. 1990). Such density estimates were made for 9 grizzly bear and 1 black bear populations in Alaska in a variety of habitats and over a range of bear densities from 6.7-380 bears/ $1,000 \text{ km}^2$ (Miller et al. 1987, Barnes et al. 1988, Schoen and Beier 1989, Miller and Sellers 1989, Miller 1990a, Ballard et al. 1990, Schwartz and Franzmann in prep.). Not all of the problems associated with using these techniques have been resolved. The best methods for dealing with capture bias, small sample sizes, and extrapolation of results to larger areas need additional study. A correction factor for small sample bias in such estimates was developed by Liberhardt (in press).

Other approaches to estimating bear density are based on movements of radio-marked bears (Rogers 1977, Hughie 1982, Reynolds et al. 1987, Schwartz and Franzmann in prep.). Typically, these techniques involve plotting home ranges of individual bears over a study area and calculating the proportions of each home range overlapping the study area. These proportions are summed to derive a population estimate and divided by the size of the study area to obtain a density estimate. Such estimates are usually identified as minimum values because of the possibility that not all bears in the study area were radio-marked. These estimates usually do not include a variance estimate and may contain subjective elements that make them difficult to replicate by different observers. However, they may provide more accurate density estimates than capture-recapture procedures used when the size of the area occupied by the estimated population is uncertain (Hughie 1982).

In the small but politically significant populations of grizzly bears in Glacier and Yellowstone National Parks, grizzly bear population size and trend were estimated from direct observations of bears (Martinka 1971, 1974; Craighead et al. 1974; Knight and Eberhardt 1984, 1985; Keating 1986; McDonald et al. 1988; Hayward 1989). In a Montana study area, number of grizzlies was estimated by adding marked bears known present with unmarked bears seen (Aune and Brannon 1987). Systematic application of direct observation techniques may be preferable for deriving such estimates for critically small populations of grizzly bears such as in the Yellowstone area (Harris 1986). However, these approaches are too labor-intensive to be useful to managers of exploited bear populations. They also lack variance estimates, which makes it difficult to evaluate the significance of reported changes in population numbers.

Another promising approach towards estimating bear

density without marking animals was described by Dean (1987). This method employs intensive aerial surveys and a sightability correction factor to estimate number of animals missed during aerial searches.

Research aimed at developing indicators of population trend have not yet produced consistently reliable procedures. Different techniques have been used to detect changes in bear numbers (see review in Harris 1986 and discussions in Pelton et al. 1978, Phelps 1979, LeFranc et al. 1987). There are ongoing efforts to develop trend indices based on use of bait stations (D. Garshelis, Minn. Dep. of Nat. Resour., Grand Rapids, pers. commun.), scent stations (Lindzey et al. 1977, J. Beecham, Id. Dep. of Fish and Game, Boise, pers. commun.), and on track counts in Florida (J. Wooding, Fla. Game and Fresh Water Fish Comm., Wildl. Res. Lab., Gainesville, pers. commun.). In some parts of Alaska, annual aerial counts of bears are conducted at food concentration sites such as along salmon streams. Correct interpretation of such data from any 1 year requires many replicate counts (Erickson and Simff 1963). Also, the utility of counts at food concentration areas to detect population trend is questionable. Numerous bears would likely be observed in such areas long after the number of bears in less preferred habitats had declined significantly. Away from food concentration areas, high direct annual counts from aircraft may provide a useful index of trend where bear populations are dense and visibility is high. Such counts in alpine habitats are conducted in southeastern Alaska (Schoen and Beier 1989) and on Kodiak Island (R. Smith, Alas. Dep. of Fish and Game, Kodiak, pers. commun.).

Vital Rates.—Rates of birth, death, and recruitment for bear populations can only be established by research programs or by extrapolation from research. For long-lived species with low reproductive and adult mortality rates like bears, estimation of these parameters requires many years of study of >10 radio-marked females (Miller 1989). Estimates of survivorship rates based on regular locations of radio-marked animals can be calculated using procedures developed by Heisley and Fuller (1985) and Pollock et al. (1989). These procedures have been applied on populations of grizzly and black bears (Knick and Kasworm 1989, Schwartz and Franzmann in prep.). Other approaches using kill rates of tagged black bears were described by LeComt (1982), Kolenosky (1986), and Miller (1987). For polar bears and grizzly bears, mortality rate of adult females was shown to be the most critical factor in correctly estimating population growth rate or sustainable mortality rates (Knight and Eberhardt 1985, Taylor et al. 1987b).

In cases where research objectives require capture or handling of bears, the studies themselves will result in some mortalities or other stresses on bear populations. These stresses may not be significant to healthy bear populations (Ramsey and Stirling 1987), but they may make such studies inappropriate for depleted populations. Whether conducted on depleted populations or not, all proposed studies requiring handling of bears should receive adequate peer review to assure that poorly designed or implemented projects are not authorized.

Information Obtained from Simulation Studies

Information obtained from hunters, from harvested bears, and from field studies needs to be integrated into a conceptual framework or model where it can be used to make management decisions. Managers are increasingly finding mathematical models of populations to be useful tools for organizing and making decisions from such information. Computers are useful tools for examining such models as they permit managers to quickly make the lengthy and repetitive calculations needed to estimate parameters like sustainable harvest levels.

Deterministic models used to estimate sustainable harvest levels have only 1 result per set of inputs. These models are relatively simple to make. Useful deterministic models can be made by persons without programming talents using conventional spreadsheet software. Such models may introduce systematic error in species, like bears, with multi-year periods of maternal care (Taylor et al. 1987c).

Stochastic models, where life history events are assigned probabilities instead of fixed rates, are useful in examining the range of possible outcomes per set of inputs. Software useful in constructing stochastic models for species with any kind of life history has been developed by Harris et al. (1986). This software was used to evaluate sensitivity of harvest data (Harris and Metzgar 1987b) and is useful in predicting, for example, probability of survival of small populations of bears.

Deterministic models based on ANURSUS (Taylor et al. 1987a) with optional stochastic features have been developed specifically for each of the 3 North American bear species. ANURSUS attempts to mimic the dynamics of bear populations and, as a result, requires a daunting number of input parameters. The 3 species models based on ANURSUS are currently being linked and documented (M. Taylor, Northwest Terr. Dep. of Renewable Resour., Yellowknife, pers. commun.). When this is accomplished, ANURSUS can be more widely tested and used to establish management objectives based on sustainable yield.

ANURSUS was used to estimate sustainable harvest levels for adult female polar bears. Less than 1.6% of the total population of all bears could be harvested as adult females (Taylor et al. 1987b). Based on this finding sustainable harvest number can be approximated (M. Taylor, Northwest Territ. Dep. of Renewable Resour., Yellowknife, pers. commun.) as:

$$H = (N)(0.015/F),$$

where H is number of bears that can be harvested, N is total population number, F is the proportion of adult females in the harvest, and the 0.015 constant is derived from the simulation result that <1.6% population can be harvested as adult females (Taylor et al. 1987b). It follows that if the whole harvest is adult females, then harvests of 1.5% of the population can be sustained. If a proportion of the harvest is male then a larger percent harvest can be sustained. The maximum sustainable harvest rate for polar bears was estimated at 4.5%; this occurred when 33% of the harvest is female (Stirling 1988b). In the Yukon Territory, ANURSUS was used to make preliminary estimates of maximum sustainable harvest levels for male (6%) and female (2.5%) segments of regional grizzly bear populations (B. Smith, Yukon Dep. of Renewable Resour., Fish and Wildl. Branch, Whitehorse, pers. commun.).

Deterministic models were used by Bunnell and Tait (1980) to estimate sustainable mortality from all causes. When natural mortalities are subtracted separately, such models estimate sustainable harvest levels. The consequence of error simulation discussed earlier illustrates this application. With the generous estimates of reproductive rates and survivorship from natural mortality used to estimate population recovery period (Table 1), maximum sustainable harvests were estimated at 7.8% for grizzly bears older than 2.0 and at 15.9% for black bears >1.0 (Table 3). These were converted to estimates of sustainable harvest of the whole population using typical values for mortality of cub and yearling grizzly bears and cub black bears (Bunnell and Tait 1985). Under these conditions and assumptions, maximal sustainable annual hunting mortality was 5.7% for grizzly bears and 14.2% for black bears (Table 3). Elsewhere this approach was used to estimate that sustainable harvests for Yukon grizzlies was 2-3% of the population (Sidorowicz and Gilbert 1981). McCullough (1981, 1986) estimated higher sustainable harvest levels than other models by incorporating density-dependent effects on recruitment. There is both direct and indirect evidence for such relationships (Rogers 1983; Kemp 1972; Stringham 1980, 1983; Young and Ruff 1982; Schwartz and Franzmann in prep.). In my view, however, these relationships are as

yet too poorly understood to be safely incorporated into estimates of sustainable harvest levels for hunted populations.

Estimates of sustainable harvest rates derived from models may be compared with calculated harvest rates derived from kill numbers and population estimates. In cases where different sexes have different vulnerability to hunters, population harvest rate can be estimated directly from information on the sex and age composition of the population (Bunnell and Tait 1985) or harvest (Fraser et al. 1982). Such comparisons should be viewed skeptically especially when age distributions are not stable (Caughley 1974, 1977; Harris 1984).

Harvest Controls

Managers have numerous regulatory tools for influencing the number or composition of bears harvested (Phelps 1979; Harger 1978). The effectiveness of any particular tool will vary among areas depending on hunting conditions and the type and motives of the hunter.

Seasons and Bag Limits. Number of bears taken by hunters can usually be reduced by shortening seasons and increased by lengthening seasons. However, season length works to reduce kill only to a point; in Pennsylvania, 736 black bears were taken in a 1979 open hunting season only 1 day long (Lindzey et al. 1983). A similar number are currently being taken with a 3-day season (G. Ali, Pa. Game Comm., Moscow, pers. commun.). Seasons can be held periodically instead of shortened. On the Alaska Peninsula in southwestern Alaska, grizzly bear hunting has been allowed only on alternate years in an effort to reduce harvest and maintain open hunting (Sellers and McNay 1984).

Shorter seasons may give managers just as many bears killed by hunters in a shorter time, hunting under more crowded conditions. When this occurs, managers may choose to limit the number of hunters by issuing permits. Hunting by limited permit can augment the quality of the

Table 3. Estimated sustainable yield from maximally productive populations of grizzly and black bears (input parameters reported in Miller [1989]).

Annual hunting rate for initial stabilized population of grizzly bears (>2.0 years-old) and black bears (>1.0 years-old)	7.8%	15.9%
Equivalent hunting rate for total population (all ages)	5.7*	14.2%*

* Total population estimated from number of 2-year olds by assuming yearling and cub mortality rates of 0.29 and 0.15, respectively, for each sex.

** Total population estimated from number of yearlings by assuming cub mortality rates of 0.22 for each sex.

hunting experience and, depending on number issued, may serve to maintain trophy bears in the population.

In some parts of Alaska, special permits and seasons are also used to minimize damage by and danger from grizzly bears that enter rural villages. By providing for these bears to be taken legally, managers achieve more accurate records on kill rates and allow the public to effect control actions that would otherwise have to be accomplished at public expense.

Seasons can also be adjusted to influence the sex of bears taken. This is particularly true during spring seasons because male bears tend to leave dens earlier than females, move greater distances, are not accompanied by cubs, and spring hunters may be more selective for large (male) bears (O'Pezzo et al. 1983, Schoen et al. 1987, Miller 1990b, Van Daele et al. 1990). During spring grizzly bear seasons in Alaska (1984-1988), 74% of grizzly bears taken ($n = 2,563$) were male compared to 55% of bears taken in fall seasons ($n = 2,963$) (ADF&G unpublished data). A similar pattern was evident for black bear where 75% of spring bears harvested during 1984-1988 were male ($n = 4,691$ bears killed) compared to 64% in fall harvests ($n = 2,887$). In some areas, polar bears killed in seasons open during the den entrance and emergence period are more likely to be females because dens are typically on land, which may be near villages of native hunters, and only pregnant females use dens (Stirling 1986, Kolenusky 1987). In parts of Canada pregnant females are protected from hunting by delaying opening of hunting until 1 December, after the den entrance period (Stirling and Calvert 1985). Black bear tracking studies in Maine revealed that black bears are likely to be distant from their breeding ranges during early fall seasons. The geographic distribution of kill at such times would not, as a result, accurately depict the origins of harvested bears (Hughie 1982).

A chronology of sex ratio in kill of grizzly bears harvested in a portion of southcentral Alaska was given by Miller (1990b). There was little change in sex ratio of kill over time during fall seasons, but there was an increase in the proportion of females killed as the spring season progressed. This suggested that the last part of spring seasons should be eliminated if hunter kills need to be reduced. However, 2-4 times as many females are killed during each of the first 2 weeks of September than during any week of the spring seasons. Also, the percentage of females in the kill is higher in the early fall than at any other time of the year (Miller 1990b). In this area, more females would be protected from hunters if the first 2 weeks of the fall season were closed than could be accomplished by closing the whole spring season.

Bag limits can also be adjusted to influence the number of bears taken. In most of Alaska, grizzly bear bag limits are 1 per 4 years. The multi-year bag limit serves to make hunters more selective as by taking a bear they forego the opportunity to take a better bear in subsequent years. In Alaska's Game Management Unit 13, grizzly bear bag limits were changed from 1 per 4 years to 1 per year during fall seasons in 1982-1986 and harvests averaged 81 bears per season (range 59-96). When bag limits were 1 per 4 years, fall harvests were lower averaging 60 bears (range 40-73) in the 5 years before the change and 53 (range 48-58) bears per season in the 2 years after the change (ADF&G unpublished data).

Increase in reported kill for certain areas may result from misreporting by hunters. This may occur when areas with multiple-year and annual-year bag limits are mixed. Differences in bag limits and seasons give hunters incentives to report location of their kills incorrectly. In Alaska, an investigation by Fish and Wildlife Protection Officers resulted in the prosecution of a guide who had misreported the location of at least 25 grizzly bears killed by himself, his relatives, and his clients during 1 season. Half of these were wrongly reported as having been taken in areas with a 1 per year bag limit when they had, in fact, been taken in an area with a 1 per 4 year bag. Such misreporting can result in serious management error in circumstances where managers rely on accuracy in these statistics.

Another way to affect bear harvests is to time bear seasons to occur at the same time as hunts for other species. In some areas harvests will be increased if hunters can take bears incidental to hunts designed primarily to take ungulates. This approach has been used in a number of different areas to influence taking black bears (Burk 1977) as well as grizzly bears in Alaska.

Closed Areas. Areas closed to hunting are also a potentially useful tool for managers. Closed or lightly hunted reservoir areas can be sources of surplus animals that immigrate to open or more accessible areas where they can be hunted (Beecham 1986). To be effective such areas must be large.

Methods, Means, and Legal Bear Definitions.—Besides season adjustments and limited entry systems, managers use restrictions on methods and means of hunting to influence harvest. These include restrictions on weapon type, transportation methods, use of attractants like bait, and use of dogs. In Michigan, the age of black bears taken by hunters using dogs was older than for hunters not using dogs (Harger 1978). However, regulations that permit baiting or hunting with dogs could result in adverse population impacts if hunters select for fe-

males, which are more likely to "tree" when chased by dogs.

One of the most effective ways to maximize sustainable harvest of bears with minimal influence on the reproductive capability of the population is to direct hunter harvest away from adult females by prohibiting shooting females accompanied by offspring. Where female bears produce new litters every 2 or 3 years, adult females are vulnerable only 1/2 to 1/3 as frequently as males. Experiments are ongoing in the Yukon Territory to direct the harvests of outlitters away from female grizzly bears by giving them incentives to harvest males (Smith 1990). Clearly, it is difficult to differentiate between sexes of bears but it will be done more often if hunters have incentives to do so. In Ontario it was shown that not all females contribute equally to reproduction (Kolenosky 1990). Protection of maternal black bear females, which are producing the bulk of recruits, is especially important when this is the case (Kolenosky 1990).

Commercialization and Restrictions by Class of Hunter. Limitations on commercial use of bear parts is a useful tool in preventing excessive harvests. Commercial exploitation of wildlife has the potential to reduce and eliminate wildlife populations and species quickly (Geist 1988). The Lacey Act of 1900 in the United States was a largely successful effort to stop the trend of commercial overexploitation of many wildlife species and populations (Trefethen 1961). In many areas the sale of black or grizzly bear hides or parts, such as gall bladders, is illegal as is the sale of polar bear hides. These restrictions reduce harvests over what would occur if commercial sales of bear parts were allowed (Geist 1988). Commercial sales of bear parts could be allowed in some states without creating local management problems, but this may exacerbate problems elsewhere by giving lawbreakers the ability to claim the parts came from somewhere sales were legal.

Regulations designed to benefit or restrict special groups of hunters such as resident, non-resident, native, sport, trophy, or subsistence hunters can be used to constrain harvests. As an alternative to using limited entry permits, such regulations allow only certain classes of hunters to participate. This is the system in effect for polar bear in both Canada and the United States where only indigenous people have hunting rights.

DISCUSSION

In most areas, bear population management has evolved from efforts to reduce bear numbers to objectives based on maintenance or augmentation of population numbers.

The ability of managers to maintain or increase bear population numbers successfully is limited by 4 major constraints.

The first constraint is adequate protection of bear habitat. This topic is treated elsewhere (McLellan and Shackleton 1988, McLellan 1990, Malison 1990, Schoen 1990).

The second constraint on bear population management is political. Bear population managers are pressured by many special interest groups, frequently with diametrically opposed objectives. In Alaska, for example, subsistence and sport hunters frequently pressure managers to reduce populations of bears and other predators. On the other extreme are groups that agitate to reduce or eliminate hunting. One such group managed to eliminate the black bear hunting season in California in 1989 (D. Koch, Calif. Dep. of Fish and Game, Sacramento, pers. commun.). Wildlife managers must spend an increasing amount of their personnel and financial resources dealing with the demands and proposals of special interest groups. These expenditures represent resources that are diverted from habitat and population management programs. Some groups, commonly those opposed to hunting, even target resource management agencies as the problem. These activities reduce public confidence and support for management efforts. An important challenge facing wildlife managers is to direct the activities of these groups into activities that increase support for soundly based management. This is easier to say than to do. Clearly, however, in the North American political system, the concerns of such groups cannot be ignored without ultimate counter-productive consequences. Although it may be frustrating at the time, it will help if these special-interest groups are involved in the development of management plans. This provides a forum where their concerns can be heard by managers and managers' concerns can be heard by them.

There appears to be more political will to protect remnant populations of bears than there is to reestablish bears in areas where they have been eliminated. Although grizzlies have been eliminated from 99% of their former range south of Canada (Servheen 1987 cited by Junkel 1987), there is little interest in reestablishing them in places like California, Colorado, or Arizona (Brown 1985). In Texas much of the public is opposed to management actions that would result in a significant increase in black bear population numbers or distribution (C. Winkler, Tex. Parks and Wildl. Dep., Austin, pers. commun.). Reintroduction of bears into an area where they have been eliminated is a positive action that will provoke some opposition. In North American political

systems, it appears to be more difficult to take action than to do nothing. Thus, it is important to assure that the *status quo* includes bears.

The third constraint is the technological tool kit available for use by managers. Many of the tools used by managers to assess the success or failure of bear management strategies lack precision, estimates of variability, or produce potentially biased results. It is easier to detect potential sources of bias and imprecision in analyses of bear populations than it is to develop approaches without these flaws. Unfortunately, the decisions managers have to make do not disappear just because the information available has uncertain accuracy or precision. In making these decisions, however, managers should incorporate the limitations of the data into their management strategies. Usually this will mean setting management objectives and guidelines on the conservative side of what might be estimated to be optimal. The costs associated with unintended population declines and the difficulties of detecting such declines until they are far advanced mandate a conservative approach to bear population management.

The fourth major constraint to population management is financial. Some of the technological constraints of existing bear population management techniques can be overcome if adequate funds were available. Where the commitment to spend the necessary money is lacking, bear population managers have little choice but to implement conservative management strategies.

ABSTRACT

We produced three, statewide, inductive habitat suitability models and population estimates for mountain lions for New Mexico. The first two models used a binary logistic regression to produce the linear combination of habitat variables that best predicted the distinction between either (1) mountain lion harvest locations and random points; or, (2) gps collared mountain lion locations and random points. The third model was produced by combining the mapped results of the first two models by adding the “excellent” and “good” habitat from the collar model to the harvest model. The models produced by binary logistic regression were entered into Raster Calculator in ArcGIS to produce maps of habitat suitability state wide. Habitat suitability was simplified to 5 categories (quintiles) using Spatial Analysis, Reclassify, in ArcGIS. Finally, the area of each habitat suitability class for each mountain lion management zone was multiplied by plausible mountain lion densities (derived from the literature) to produce an estimated range of mountain lion population sizes. The harvest, collar, and combined models predicted 8%, 16%, and 60% greater statewide mountain lion population estimates, respectively, than the current New Mexico Department of Game and Fish population estimates based on a deductive model. (Note: The higher population estimate produced by our harvest model is not uniform across mountain lion management zones. Approximately, half of the management zones were predicted to have smaller populations than previously predicted.) Our harvest model is the most conservative of the three and is in close agreement, at the state level, with the deductive model. We suggest that the harvest model be the primary source for guiding an adaptive management approach to mountain lion conservation in New Mexico.

INTRODUCTION

Information on the abundance and distribution of any species is essential for its responsible management. According to the New Mexico Department of Game and Fish Strategic Plan for 2008 through 2012, the mission of the agency is:

“To provide and maintain an adequate supply of wildlife and fish within the state of New Mexico by utilizing a flexible management system that provides for their protection, propagation, regulation, conservation, and for their use as public recreation and food supply.”

Meeting these objectives for mountain lions poses significant challenges as these animals are secretive and occur at relatively low densities, making it difficult to conduct population counts. Even the result of such a census may be primarily local in application. However, the density estimates obtained from local studies is a critical starting point in understanding mountain lion population sizes and distribution.

To address these needs in mountain lion management alternative approaches to direct population counts are used. One increasingly useful approach is the use of habitat or niche modeling with GIS technology (Hirzel et al. 2006). The Cougar Management Guidelines Working Group (2005) suggests this technique as a primary means of planning statewide mountain lion management programs. This approach has been used to predict mountain lion habitat dispersal corridors and habitat patches in the Midwest (LaRue and Nielson 2005) as well as mountain lion population distribution and dispersal routes in Riverside County California, and to

inform mountain lion management in New Mexico (Negri and Quigley 2010). These models have employed a deductive approach using expert opinion regarding mountain lion habitat preferences. Actual location data may be used to produce more objective, and possibly more accurate models. Location data may come from hunter harvest records or from VHF or GPS collars worn by free roaming mountain lions. The resulting models are inductive, generalizing habitat preferences from a subset of the mountain lion population across a broad geographic area. It should be noted that models built from harvest data may also be biased by hunter distribution and success. Data from collared mountain lions can address some of these biases. Perhaps the greatest utility of these models is that they represent testable hypotheses about the distribution and density of mountain lions that can inform an adaptive management approach.

Our primary goal in this project is to provide a scientifically robust estimate of mountain lion status across the state, based on actual mountain lion locations derived from harvest data and GPS collared mountain lions. Our objectives were to: (1) Identify and map habitat quality, defined by probability of mountain lion occurrence, in five quality categories, excellent, good, moderate, fair, and poor; (2) quantify the total area of each category of habitat quality in square kilometers by game management unit and mountain lion management zone; (3) map the statewide distribution of each habitat type; and, (4) project a statewide mountain lion population estimate, broken down by hunt unit and mountain lion management zone, based on the area and extent of habitat categories and reasonable mountain lion densities derived from the scientific literature.

METHODS

Statistical Approach

We used an inductive model building approach, using mountain lion locations, and their associated habitat characteristics to make generalizations about mountain lion habitat preference and suitability. Specifically, we used a binary logistic regression to produce the linear combination of habitat variables that best distinguished between random locations and mountain lion locations across the state of New Mexico. We made this approach more rigorous by building the model with a subset of locations and then testing the accuracy of the model at identifying the remaining points as either random or mountain lion based on associated habitat characteristics. This linear combination of variables (the model) was then entered into ArcGIS Raster Calculator to produce habitat suitability maps. We actually constructed three models: we used a binary logistic regression to distinguish between harvest locations and random locations to produce one model. We used the same approach to distinguish between random locations and collared mountain Lion locations to produce a separate model. Finally, we combined these models by adding the 'excellent' and 'good' habitats from the collar model to the harvest model.

Data

In initial model building, we used two sources of mountain location data, (1) harvest and (2) GPS collar, and data on several habitat variables: (3) vegetation type, (4) topographic ruggedness, (5) slope, (6) elevation, (7) snow depth, (8) distance to paved roads, (9) distance to dirt roads, (10) elk distribution, and (11) mule deer distribution.

(1) New Mexico mountain lion harvest data was provided by the New Mexico Department of Game and Fish. Approximately, 1,684 total records from 2001 to 2009 were provided. We georeferenced 1,397 of these records for the model. There are inherent, but unavoidable, biases to harvest data in the construction of harvest data. For example, proximity to roads may seem to be an important quality for suitable mountain lion habitat. When, in fact, it is hunter access that drives the importance of this variable. A second potential source of error is the accuracy of the georeferencing. Caution is warranted in the use and interpretation of models based on harvest data.

(2) We obtained GPS collar data from 10 free roaming mountain lions between 2005 and 2010. GPS locations were taken at night and reflect active habitat use. We used approximately, 13,000 GPS locations for model building. A bias inherent to the use of these data is their restricted geographic application. As all of these mountain lions were in the southcentral portion of New Mexico, below 7,000 ft, the resulting model would not predict that habitat types outside of this region would be suitable mountain lion habitat. (eg mixed coniferous forest). The advantage of these data is that they show mountain lion habitat use outside of areas frequented by hunters.

(3) We simplified vegetation classifications provided by the Southwest Regional GAP Analysis, as described in "Landcover descriptions for the Southwestern Regional GAP Analysis project" compiled by NatureServe, 2004. The relationship between the vegetation categories used for the model and the original SWReGAP categories can be found in Appendix I. For use in the raster calculator, we created a separate raster for each vegetation type, giving pixels a value of either zero (not the specified vegetation type) or one.

(4) We created an index of topographic ruggedness by using the USGS 30 meter National Elevation Dataset for New Mexico available from the RGIS website. (<http://rgis.unm.edu/intro.cfm>). The following equation was applied: $TPI = \frac{SQR(FOCALSTD([DEM], CIRCLE, X))}{X}$, where X is the number of pixels in the radius of the circle. In this way we created four rasters of topographic ruggedness at four scales: 120, 240, 480, and 960 meters, respectively.

(5) Slope was derived from the USGS 30m DEM as percentage slope using ArcGIS Spatial Analyst.

(6) Elevation was taken from the USGS 30m DEM

(7) Snow depth was obtained from the National Climatic Data Center which is within the National Oceanic and Atmospheric Administration (NOAA)

(<http://hurricane.ncdc.noaa.gov/cgi-bin/climaps/climaps.pl>). National data representing average annual snowfall were used for this input.

(8) Distance to Paved Roads was calculated from the TIGER 2008 roads dataset. Roads were obtained from the U.S. Census 2008 TIGER shapefiles website (<http://www2.census.gov/cgi-bin/shapefiles/national-files>). Paved roads were extracted and distance to roads was calculated using the Euclidean Distance function in Spatial Analyst at a 30 m resolution.

(9) Distance to Dirt Roads was calculated from the TIGER 2008 roads dataset. Dirt roads were extracted and distance to roads was calculated using the Euclidean Distance function in Spatial Analyst at a 30 m resolution.

(10) We calculated a rough index of elk availability by dividing the total allowable harvest of elk for the 2010-2011 season by the area of each hunt unit.

(11) We calculated a rough index of mule deer availability by dividing the total allowable harvest of mule deer for the 2010-2011 season by the area of each hunt unit.

We entered the resulting binary logistic models (one for harvest data and one for collar data) into the ArcGIS Spatial Analyst, Raster Calculator to produce a raster in which each pixel was given a value that corresponded to the inverse odds of mountain lion occurrence. The range of pixel values in each of the resulting rasters was then simplified to 255 values using the Spatial Analyst Reclassify tool. These 255 values were then further simplified to 5 values by grouping the 255 values by quintiles and reclassifying a second time. The result, for each model, was a raster showing 5 categories of mountain lion habitat suitability (probability of mountain lion occurrence).

Next, we used Hawth's Tools, Raster Tools, Thematic Raster Summary by Polygon to calculate the area of each habitat class for each Game Management Unit (GMU). Then we multiplied each habitat type area for each GMU by a range of possible mountain lion densities, supplied by the New Mexico Department of Game and Fish (Table 1).

	Excellent	Good	Moderate	Fair
Density Range (per 100sqKm)	2-3	0.89-1.2	0.4-0.6	0.2-0.3

Table 1. Mountain lion density ranges by habitat category, provided by the New Mexico Department of Game and Fish used in the calculation of mountain lion populations.

RESULTS

In both the harvest and collar models the variables with the most significant predictive value were topographic ruggedness, at the scale of 480m, and vegetation type. The addition of other predictor variables did not significantly improve the models. In the models that follow, the lower the coefficient, the more this variable contributes to suitable mountain lion habitat. The binary logistic regression models were:

(1) for harvest data:

$$\begin{aligned} \text{Puma} = & -0.0001[\text{TRI480}] + 21.844 * [\text{acmesq1}] + 21.04 * [\text{acpsdg2}] + 21.127 * [\text{agric3}] \\ & + 22.019 * [\text{badland4}] + 21.616 * [\text{barren5}] + 22.54 * [\text{ccreosote7}] + 42.332 * \\ & [\text{cscrub8}] + 21.352 * [\text{canyon9}] + 22.277 * [\text{canmesa10}] + 42.322 * [\text{ccdunesd11}] + \\ & 20.547 * [\text{chaparral12}] + 19.583 * [\text{cliffrock13}] + 0.065 * [\text{cpshrub14}] + 42.399 * \\ & [\text{dgrasslnd15}] + 22.219 * [\text{dunes17}] + 21.857 * [\text{gpmesq18}] + \\ & 42.322 * [\text{gpsndshb19}] + 19.088 * [\text{gpfgrass20}] + 42.322 * [\text{gypgrass21}] + 21.907 * \\ & [\text{imgrass22}] + 21.9 * [\text{imbshrub23}] + 21.539 * [\text{junpgrass25}] + 42.332 * [\text{lava26}] + \\ & 19.9 * [\text{madoak29}] + 20.419 * [\text{mixconifer30}] + 20.261 * [\text{mongrass32}] + 19.962 * \\ & [\text{montshrub33}] + 42.337 * [\text{water35}] + 19.681 * [\text{pine36}] + 20.529 * [\text{pj37}] + 20.27 * \\ & [\text{playa38}] + 19.486 * [\text{ripwood42}] + 20.381 * [\text{sage44}] + 22.459 * [\text{sgprairie45}] + \\ & 21.051 * [\text{urban49}] \end{aligned}$$

Certain adjustments to coefficients were made: 0.065 coefficient for cpshrub (Colorado Plateau Shrubland) was unrealistic and resulted from small sample size. Also, the coefficients for [barren5], [playa38], and [urban49] were changed to 43 (meaning low probability of mountain lion occurrence), as breeding populations of mountain lions cannot reasonably be expected to occur in these areas.

This model correctly predicted 85% of test mountain lion harvest locations (Appendix II).

(2) for collar data:

$$\begin{aligned} \text{Puma} = & -0.0001 * [\text{TRI_480.img}] + 19.708 * [\text{acmesq1}] + 18.739 * [\text{acpsdg2}] + 20.998 \\ & * [\text{agric3}] + 43.049 * [\text{badland4}] + 43.654 * [\text{barren5}] + 20.002 * [\text{ccreosote7}] + \\ & 19.724 * [\text{cscrub8}] + 46.082 * [\text{canyon9}] + 22.311 * [\text{ccdunesd11}] + 18.515 * \\ & [\text{chaparral12}] + 17.559 * [\text{cliffrock13}] + 19.886 * [\text{dgrasslnd15}] + 20.735 * [\text{dunes17}] \\ & + 42.769 * [\text{gpmesq18}] + 42.412 * [\text{gpsndshb19}] + 42.409 * [\text{gypgrass21}] + 20.603 * \\ & [\text{imgrass22}] + 22.279 * [\text{imbshrub23}] + 46.184 * [\text{jungrass25}] + 42.46 * [\text{lava26}] + \\ & 21.677 * [\text{madoak29}] + 25.507 * [\text{mixconifer30}] + 43.691 * [\text{mongrass32}] + 44.049 * \\ & [\text{montshrub33}] + 42.489 * [\text{water35}] + 21.742 * [\text{pine36}] + 19.870 * [\text{pj37}] + 19.231 * \\ & [\text{playa38}] + 1.215 * [\text{ripherb39}] + 15.223 * [\text{ripwood42}] + 44.265 * [\text{sage44}] + 42.479 \\ & * [\text{sgprairie45}] + 42.496 * [\text{urban49}] \end{aligned}$$

This model correctly predicted 99% of test collared mountain lion locations. (Appendix III)

The three resulting models, from harvest data, collar data, and the combination of the two, predict successively larger statewide mountain lion populations respectively. The harvest data model is the most conservative, predicting a statewide population of mountain lions between 2,099 and 3,122 (Table 2, Figure 1). The collar model predicts a statewide population between 2,253 and 3,122 (Table 2, Figure 2). The combined models, in which excellent and good mountain lion habitat predicted by the collar model was added to the harvest model, predicts a statewide population between 3,197 and 4,732 (Table 2, Figure 3). The real number of mountain lions statewide likely lies between the harvest model and harvest + collar population estimates. As the harvest model is the most conservative, we suggest that it be used for management decisions.

Table 2. This table compares mountain lion population estimates by mountain lion management unit across the three models, harvest, collar, and harvest and collar (Harvcol) combined. Note that mountain lion population estimates for the “T” (Tribal) areas of the state are not included in the estimate.

For detailed calculations of mountain lion population size by GMU across all three models see Appendix IV.

DISCUSSION

The harvest data model, the most conservative of the three models, predicts a statewide mountain lion population approximately 8% larger than the current NMDGF mountain lion population estimates. It is perhaps most notable, that the two estimates are so similar. The harvest model's higher statewide estimate is not the result of uniformly higher estimates across GMU's. Approximately, half of the units were predicted to have fewer mountain lions by the model than previously predicted by NMDGF. The fact that tribal areas were not included in the statewide population estimate makes the harvest model more conservative.

The accuracy of any model is only as good as the data used to construct the model. There are at least three points of potential issue with the data used for these models.

First, there are inherent biases in both harvest data and GPS collar data. Harvest data may be biased by hunter access (roads) or environmental factors that increase hunter success (snow). The result of this bias is that the model may underestimate the mountain lion population in areas where there are few roads or where there is infrequent, or no, snow fall. Likewise, favored hunting areas with high success may over-estimate mountain lion populations. The GPS collar data is biased in two ways. First, because there was not a statewide distribution of collared mountain lions, the habitat selection of collared lions was limited. For example, because all collared mountain lions were in southcentral New Mexico, below 7,000 ft, obviously suitable habitat types, such as mixed conifer, are not predicted to be suitable mountain lion habitat by this model. This also, would lead to a significant underestimate of statewide populations. Second, collared mountain lions may pass through unsuitable habitat, regularly, to access favored habitats. As a result, unfavorable habitat types, such as creosote flats, may be shown by the model to be moderately suitable to mountain lion populations, causing an overestimation of mountain lion numbers. A solution to the second bias may be addressed by using only prey cache sites from collared mountain lions. Evidence of mountain lions feeding in particular habitats is stronger evidence of habitat suitability than mere location data.

A second source of concern is the accuracy of georeferenced harvest data. Whereas collar data may be accurate to the scale of meters, harvest data may only be accurate to the scale of 100's of meters or even kilometers. The result may be that truly unfavored habitat types appear to be favored. The best remedy for these inaccuracies is sample size. With 1,400 georeferenced records, we can be relatively confident that this is not a significant source of error in these models.

A final area of potential inaccuracy, in calculating population size, is the choice of density ranges. The density of mountain lions has been accurately measured in a number of

intensive field studies. However, it is difficult to compare density estimates across studies due to differences in approach. Recently, Quigley and Hornocker (2010) provided a summary of density estimates across several studies, ranging from 0.32 to 7.3 per 100 sqKm. The density estimates used in these models are conservative, ranging from 0.2 to 3 per 100sqKm. Mountain lion densities in New Mexico might exceed this top range in productive habitats. Recently, four resident adult females and two resident adult males were observed frequenting a 100 sqKm camera study area in the eastern piedmont of the Black Range.

The primary utility of population estimate models is to serve as hypotheses to guide adaptive management practices. There are at least two methods for testing the accuracy of these model predictions: (1) remote camera mark-resight population estimates in select habitats and (2) monitoring the sex and age distribution of harvested lions as per the findings of Anderson and Lindzey (2005).

ACKNOWLEDGEMENTS

We would like to thank Rick Winslow and the New Mexico Department of Game and Fish for providing the opportunity to contribute to responsible, science based, conservation of mountain lions in New Mexico. We would also like to thank the NMDGF conservation officers who have diligently collected accurate location data from harvested mountain lions. Special thanks goes to Megan Pitman and Michael Jiang for their many, many hours of tedious georeferencing.

APPENDIX IV

Detailed calculations of mountain lion population size by GMU. H, C, and HC are abbreviations for harvest model, collar model, and harvest and collar models combined, respectively. Numbers in columns with “Excellent”, “Good”, “Moderate”, “Fair”, and “Poor” represent units of 100 sq Km area of that habitat quality category predicted by each model. These are then arranged by row for each GMU. For example, the harvest model predicts 960 sq Km of excellent mountain lion habitat in GMU 2C. The numbers in the columns with “hi” and “lo” represent the total of hi and lo density estimates for each habitat quality category multiplied by the area of that habitat quality category for each GMU. For example, the harvest model predicts between 24 and 36 resident adult mountain lions in GMU 2C.

GMU	Cougar_Zone	Havest lo	Harvest hi	Collar lo	Collar hi	Harvcol lo	Harvcol hi	H Excellent	H Good	H Moderate	H Fair	H Poor	C Excellent	C Good	C Moderate	C Fair	C Poor	HC Excellent	HC Good	HC Moderate	HC Fair	HC Poor

SINK POPULATIONS IN CARNIVORE MANAGEMENT: COUGAR DEMOGRAPHY AND IMMIGRATION IN A HUNTED POPULATION

HUGH S. ROBINSON,^{1,3} ROBERT B. WIELGUS,¹ HILARY S. COOLEY,¹ AND SKYE W. COOLEY²

Abstract. Carnivores are widely hunted for both sport and population control, especially where they conflict with human interests. It is widely believed that sport hunting is effective in reducing carnivore populations and related human–carnivore conflicts, while maintaining viable populations. However, the way in which carnivore populations respond to harvest can vary greatly depending on their social structure, reproductive strategies, and dispersal patterns. For example, hunted cougar (*Puma concolor*) populations have shown a great degree of resiliency. Although hunting cougars on a broad geographic scale ($>2000\text{ km}^2$) has reduced densities, hunting of smaller areas (i.e., game management units, $<1000\text{ km}^2$), could conceivably fail because of increased immigration from adjacent source areas. We monitored a heavily hunted population from 2001 to 2006 to test for the effects of hunting at a small scale ($<1000\text{ km}^2$) and to gauge whether population control was achieved ($\lambda \leq 1.0$) or if hunting losses were negated by increased immigration allowing the population to remain stable or increase ($\lambda \geq 1.0$). The observed growth rate of 1.00 was significantly higher than our predicted survival/fecundity growth rates (using a Leslie matrix) of 0.89 (deterministic) and 0.84 (stochastic), with the difference representing an 11–16% annual immigration rate. We observed no decline in density of the total population or the adult population, but a significant decrease in the average age of independent males. We found that the male component of the population was increasing (observed male population growth rate, $\lambda_{\text{OM}} = 1.09$), masking a decrease in the female component ($\lambda_{\text{OF}} = 0.91$). Our data support the compensatory immigration sink hypothesis; cougar removal in small game management areas ($<1000\text{ km}^2$) increased immigration and recruitment of younger animals from adjacent areas, resulting in little or no reduction in local cougar densities and a shift in population structure toward younger animals. Hunting in high-quality habitats may create an attractive sink, leading to misinterpretation of population trends and masking population declines in the sink and surrounding source areas.

Key words: attractive sink; carnivore; cougar; hunting; immigration; mortality; population dynamics; *Puma concolor*; source–sink; survival.

INTRODUCTION

Carnivores are widely hunted for sport and population control, in part to reduce their effect on prey and to reduce conflicts with humans and their property (Treves and Karanth 2003). It is widely believed that sport hunting can be effective to reduce carnivore populations and related human–carnivore conflicts while maintaining viable populations (Strickland et al. 1994). How carnivore populations respond to harvest can vary greatly depending on their social structure, reproductive strategies, and dispersal patterns (Frank and Woodroffe 2001). Dispersal, in particular, can have significant ramifications (both stabilizing and destabilizing) on

population dynamics (Hanski 2001). Density-dependent dispersal may stabilize populations as immigration and emigration counterbalance between hunted (sink) and nonhunted (source) populations. However, many carnivore species display high levels of intrinsic dispersal of predominantly juvenile males, regardless of natal population density (Chepko-Sade and Halpin 1987, Zimmermann et al. 2005). Such intrinsic dispersal may mimic mortality if emigration is not reciprocated by immigration from neighboring populations, thereby greatly increasing the risk of sudden and dramatic decline in both source and sink populations (Howe et al. 1991). If carnivore management plans do not take into account the specific response of individual species and geographic scale of harvest, they may be more detrimental to the greater population than intended, or ineffective for local population control (Reynolds and Tapper 1996, Frank and Woodroffe 2001, Baker and Harris 2006).

Cougars (*Puma concolor*) are widely hunted for both sport and population reduction in western North America (Cougar Management Guidelines Working Group 2005:71). Although high harvest during the 18th and 19th centuries caused local extinctions and reduced the species' range (Nowak 1976), some extant populations have sustained annual harvest levels of 15–30% of resident adults (Murphy 1983, Ross and Jalkotzy 1992). Other populations have rebounded quickly following single perturbations (Lindzey et al. 1992, Logan and Sweanor 2001:171) or after harvest rates were lowered (Anderson and Lindzey 2005).

The resiliency of cougar populations is thought to depend on high levels of juvenile immigration from neighboring areas and philopatric recruitment of female offspring (Lindzey et al. 1992, Sweanor et al. 2000). If such replacement or compensatory immigration occurs, localized hunting pressure may actually be ineffective or even counterproductive for population control. Although hunting cougars on a broad geographic scale ($>2000 \text{ km}^2$) can reduce cougar densities (Lambert et al. 2006), hunting of small areas ($<1000 \text{ km}^2$), as currently prescribed by many government agencies to reduce local populations and cougar–human conflicts (e.g., Oregon Department of Fish and Wildlife 2006:39, Wyoming Game and Fish Department 2006:19), may simply create a localized “sink,” a population characterized by its dependence on immigration to maintain stability (Pulliam 1988, Thomas and Kunin 1999). In cougar populations, younger individuals are most often involved in conflicts with humans (Beier 1991). High immigration and recruitment in sinks may shift the population structure toward younger animals, perhaps confounding the stated management goal of reducing cougar–human conflicts.

We tested the following hypotheses relative to the effects of hunting at a small scale ($<1000 \text{ km}^2$) to determine if hunting reduced population size, or simply created a sink with increased immigration. The hunting control (closed-population) hypothesis predicts that emigration and immigration are equal, that cougar harvest is an additive mortality source, and that harvest will reduce cougar densities in a given area. The compensatory immigration (metapopulation source–sink) hypothesis predicts that cougar removal in small areas will result in high levels of immigration and recruitment, resulting in little or no reduction in cougar densities and a shift in population structure toward younger animals. We intensively monitored a hunted cougar population in northeastern Washington State, USA from late 2001 to 2006 to determine overall population growth, male and female population growth, density, and age structure. To determine immigration rate, we compared the growth rates predicted by a standard closed-population survival/fecundity model (calculated from a Leslie matrix) based on radio-collar data, with growth rates determined from the total known/real open population.

FIG. 1. Study area (Game Management Unit 105) surrounded by the Ferry-Okanogan (FO) and Stevens-Pend Orielle (SPO) cougar management zones of Washington State, USA, and by Region 4 (R4) and Region 8 (R8) of British Columbia (BC), Canada. Cougar management zones and Wildlife Regions are composed of smaller Game Management Units (i.e., 105, 8-15).

STUDY AREA

Our study was conducted in Washington State's Game Management Unit 105, an area of 735 km^2 . This triangular-shaped mix of public (Colville National Forest) and private land is bounded to the north by the Canadian border, and to the east and west by the Columbia and Kettle rivers, respectively (Fig. 1). The area is located in the Northern Rocky Mountain (USA) Ecoprovince (Bailey 1995) and is characterized by rugged terrain with numerous ridges (1500–2000 m) interspersed by low valleys (500 m). Average winter temperature (November–March) is 4.2°C and average summer temperature (April–October) is 23.8°C . Precipitation averages 439 mm/yr , with the majority falling in winter. Between November and March there is an average of 8.6 cm of snow on the ground at an elevation of 500 m .

Mixed evergreen–deciduous forest dominates the landscape. Upland overstory species include Douglas-fir (*Pseudotsuga menziesii*), western hemlock (*Tsuga heterophylla*), ponderosa pine (*Pinus ponderosa*), and subalpine fir (*Abies lasiocarpa*). At the lowest elevations and driest south-facing slopes, grasslands dominate, with some areas cleared and irrigated for alfalfa (*Medicago sativa*) production.

White-tailed deer (*Odocoileus virginianus*) are the most abundant ungulate, but mule deer (*Odocoileus hemionus*), elk (*Cervus elaphus*), and moose (*Alces alces*) are also present. Populations of both species of deer, the main prey for cougars in the area, remained constant during the study period (Cooley et al. 2008). Common

predator species besides cougar include coyote (*Canis latrans*), black bear (*Ursus americanus*), and bobcat (*Lynx rufus*).

In 1996 the use of hounds to hunt cougars was banned in Washington State by public initiative. State wildlife officials tried to maintain hunting pressure on the population by increasing the “bag limit” from one to two animals for non-hound hunters and by making cougar hunting tags more accessible to the public. In 2000, in part because of increased public concern over cougar–human conflicts, Washington reinstated a limited hunt using hounds (Washington Substitute Senate Bill 5001). This “public safety cougar removal” targeted cougars in specific areas with numerous public complaints (Beausoleil et al. 2003). In 2004, an additional limited hound season was introduced in five counties in northern Washington (Washington Substitute Senate Bill 6118). Our study area was included in this new hound season as part of the Stevens-Pend Oreille cougar management zone that had a quota of 38 total cougars or 15 females. During the 2004–2005 season, 33 cougars were harvested before the female quota was reached and the season was closed. Cougar populations and harvest levels, including neighboring portions of British Columbia, have declined across the region since a peak between 1999 and 2001 (Lambert et al. 2006); see Fig. 2.

METHODS

Cougar capture

From December 2001 to April 2006, we attempted to radio-collar all cougars in the study area that were at least one year old, following the method first described by Hornocker (1970). Immobilized cougars were sexed, aged, and examined to gauge general health. Animals were fitted with numbered ear tags and either a VHF (Advanced Telemetry Systems, Isanti, Minnesota, USA) or GPS (Lotek Wireless, Newmarket, Ontario, Canada) radio collar equipped with mortality sensor on a 7-h delay. Age of adults was based on gum recession (Laundre et al. 2000). Young animals that did not show any gum recession were aged based on known birth date, size, pelage, movements, and social status. Cougar dispersal occurs between 10 and 33 months (Sweaner et al. 2000); therefore, animals still traveling with their mothers when first encountered were assigned an age of between 3 and 18 months based on their size. Animals traveling with siblings when collared, and independent animals that continued to disperse after being collared (establishing a home range distinct from their capture location), were assumed to be juveniles in the early stages of dispersal and were ascribed an age of 21 months. Independent animals that established a home range that included their capture location were assumed to have completed dispersal and were classified as subadults, assigned an age of 25 months.

All animals (collared and uncollared) that were shot in the study area as part of the sport harvest or as problem wildlife were sexed and aged during a

compulsory inspection by Washington Department of Fish and Wildlife staff. Hunters were required to provide intact proof of sex (genitalia) on cougar pelts no later than 5 days post harvest. A premolar was extracted as part of this compulsory inspection and was sent to the Matson Lab (Milltown, Montana, USA) for aging by analysis of cementum annuli. We performed a paired *t* test (estimated age of collared cougars by gum recession and by cementum annuli following harvest) to test for agreement between the two aging methods. Simple linear regression was used to examine the trend in age structure (Zar 1999:324).

Based on their age when collared or first observed, as in the case of kittens and juveniles, study animals were placed in one of the following four age categories: kittens (1–12 months), juveniles (13–24 months), subadults (25–36 months), and adults (≥ 37 months). Maximum age was set at 10 years or 120 months (see *Results*).

Survival

Cougars give birth year-round (Murphy et al. 1999:80, Logan and Sweaner 2001:88) and therefore do not fit the normal “birth pulse” method of calculating age-specific annual survival based on a calendar (e.g., January–January), or biological (e.g., June–June) year. We calculated age-specific radio-days and survival for each collared animal, based on a dynamic year determined by their age at capture. For example, an animal collared in January at an age of 21 months contributed four months of radio-days to juvenile (13–24 months) survival and was assumed to become a subadult (25–36 months) in May, becoming an adult (37–48 months) the following May, and so on.

Annual age-specific survival rates were calculated based on daily survival rates (Heisey and Fuller 1985) by grouping all animals in each age category across the entire study period (December 2001 to August 2006). Radio-days of adult males were grouped from adult 4 years to adult 10 years, whereas female adult survival was divided into two categories, adult 4–5 years and adult 6+ years. This grouping was based on mortality sources and was used to reduce variance within groups. In a hunted population, males have an equal probability of mortality across their adult life (i.e., a 3-year-old male is as large, and therefore as desirable a trophy, as an 8-year-old male). Females, on the other hand, experience mortality causes beyond hunting that vary with age and reproductive status. Females with kittens suffer from intraspecific mortality in defense of their kittens and may sustain higher natural mortality rates as they mature (Logan and Sweaner 2001:129, Stoner et al. 2006). We used one-tailed, known-variance *z* tests to test if female survival was significantly higher than male survival and mortality rates.

No kittens were radio-collared during our study. Therefore kitten survival was based on the total number of kittens that survived divided by the total number born

FIG. 2. Total cougar harvest (all ages and both sexes) for the years 2001–2005 in the study area and neighboring region, including Washington State's Ferry-Okanogan and Stevens-Pend Orielle Cougar Management Units and portions of British Columbia's Regions 4 and 8 (see also Fig. 1).

each year. A low estimate was based solely on den visits where the number of kittens born was known. Their survival rates were based on tracks observed traveling with collared females within one year of birth. This first estimate was considered to be biased low because of the small sample obtained ($n = 12$ kittens from five dens). The high estimate was based on kittens ≤ 1 year old observed traveling with collared females ($n = 19$ kittens). This second estimate is considered biased upward because the actual number of kittens born was not known and animals that died within 3–6 months of birth (before being detected) would not have been documented. We calculated the mean of the low and high estimates to obtain what we believe to be the least biased estimate of kitten survival.

Maternity and fecundity

Maternity (mean litter size per female per year) was the mean number of kittens observed, through both den visits and tracking, divided by the total number of females observed that year (Case 2000). Fecundity rates were calculated using the average maternity rates and average adult female survival (>24 months) $F = S_F \times M_{x+1}$ (the number of females that survive in year x multiplied by their mean maternity rate the following year) (Ebert 1999).

Deterministic and stochastic growth rates

We constructed a survival/fecundity dual-sex Leslie matrix (Leslie 1945) in RAMAS GIS (Akçakaya 2002) using the calculated survival and fecundity parameters. This closed-population model assumes that immigration and emigration balance and do not affect growth rate. Females were assumed to first breed as subadults (>24 months), and fecundity was kept constant for females aged 25 months and older (Anderson 1983). We used an equal sex ratio in kittens (Logan and Sweanor 2001:69) and all animals were assumed to die before reaching age class 11 years. Beier (1996) believed that cougars become senescent at age 12 and Lambert et al. (2006) also used this age in their cougar dual-sex matrix. Furthermore, in a heavily hunted population in Wyoming, Logan et al. (1986) found few cougars ≥ 7 years old and we found no adults >9 years old in our study area (see *Results*). Deterministic population growth rate (λ_D) was derived from the Leslie matrix.

To calculate a stochastic growth rate, we used annual environmental variation in population parameters (standard deviation of survival and fecundity). Rates were calculated for each year of the study based on an August–August year. Because of small sample sizes for each sex and age class (not all age classes were present in each year), standard deviations of survival rates were calculated by pooling all age classes for each sex in each

TABLE 1. Radio-days, total mortality, and survival rate (mean \pm SD) by sex and age class for 34 radio-collared cougars (*Puma concolor*) in northeast Washington State, USA, 2002–2006.

Age class	Females			Males		
	No. radio-days	No. dead	Survival rate	No. radio-days	No. dead	Survival rate
Juvenile (13–24 months)	698	1	0.5926 \pm 0.31	785	1	0.6280 \pm 0.29
Subadult (25–36 months)	2039	1	0.8360 \pm 0.15	1083	2	0.5093 \pm 0.24
Male adult 4+ (37–108 months)				1018	3	0.3405 \pm 0.21
Female adult 4–6 (37–60 months)	3530	3	0.7332 \pm 0.13			
Female adult 6+ (61–108 months)	1883	2	0.6785 \pm 0.19			
Total (all ages)	8150	7	0.7308 \pm 0.09	2886	6	0.4678 \pm 0.15

year. Annual variation in survival, and therefore fecundity, was assumed to affect each age class equally.

An average stochastic growth rate was obtained by running 300 four-year (three-transition) population trials based on the same population parameters used in the deterministic model, but with annual environmental and demographic variation represented in a standard deviation matrix (Akçakaya 2002).

Observed growth rate

We back-calculated the life span of all cougars known to have spent time in the study area from August 2001 to August 2005 using methods described by Logan and Sweeney (2001:66) and Stoner et al. (2006). This form of census includes all population constituents, including immigrants.

Males and females were backdated differently based on their distinct dispersal patterns; males disperse a long distance from their natal home ranges, whereas females display much shorter dispersal distances, often establishing philopatric home ranges within or adjacent to their mother's range (Sweeney et al. 2000, Logan and Sweeney 2001:236, Stoner et al. 2006). Males were assumed to have immigrated into the study area at 21 months of age. Therefore, independent males that were older than 21 months when first encountered were assumed to have been present in the study area from 21 months of age. Independent females older than 21 months were assumed to have been born in the study area or to have resided in it since August 2001, whichever came first. Kittens were assumed to be present at one month of age. Juveniles and kittens traveling with adult females that were not decisively sexed or collared were divided equally between sexes (Logan and Sweeney 2001:69).

Independent animals that were treed but not collared or only had their tracks observed were not included in the population estimate because of the risk of double-counting individuals. For example, an animal that was treed but never marked may have been later harvested or captured in the study area and therefore included in the population estimate twice. This method therefore yields a minimum population estimate.

The observed population growth rate (λ_O) and sex-specific female and male growth rates (λ_F and λ_M) were determined based on the total number of cougars (adults

and kittens) each year using the formula $\lambda_x = (n_t/n_0)^{1/t}$, where λ_x is the annual finite growth rate, n_0 is the starting population, n_t is the final population, and t is the number of transitions between the start and end of the population projection (Case 2000:3).

Comparison of population growth rates

A one-tailed, one-sample t test was used to test if deterministic (λ_D) and stochastic (λ_S) growth rates were lower than the average four-year observed (λ_O) growth rate (Zar 1999:96). Immigration rate (i) was estimated by comparing the survival/fecundity model growth rates to the observed/real growth rate using the equations $i = \lambda_O - \lambda_D$ and $i = \lambda_O - \lambda_S$ (Peery et al. 2006).

Population density

We calculated density based on the total number of cougars present in the study area over the course of each year (Ross and Jalkotzy 1992, Spreadbury et al. 1996). This method may not be extrapolated to areas outside the study area, but provides a consistent measure of density among years. Simple linear regression was used to test for significant changes in density over the study period (Zar 1999:324).

RESULTS

Cougar capture

Seventy-nine animals were observed in the study area between August 2001 and August 2005. We collared 34 cougars: 19 juveniles (12 males, seven females), four subadults (two males, two females), and 11 adults (two males, nine females); see Table 1. Nineteen uncollared cougars were shot in the study area: eight females (two juveniles, three subadults, and three adults) and 11 males (two juveniles, five subadults, and four adults). Twenty-four kittens (six males, nine females, and nine unknowns) and two juveniles (one male and one female) were observed traveling with collared females but were never collared. Age determined by gum recession was not significantly different than age determined by cementum annuli in 14 samples for which both methods were used on a single animal ($t = 0.39$, $df = 13$, $P = 0.70$).

Survival and mortality

Hunting was the main cause of mortality within the population, accounting for nine of 13 deaths of study

TABLE 2. Sources and rates of mortality (mean \pm SD) and number of dead animals (in parentheses) by sex and age class for 34 radio-collared cougars in northeast Washington, 2001–2006.

Sex and age class	Mortality source		
	Depredation	Hunting	Natural
Female			
Juvenile (12–24 months)			0.4074 \pm 0.31 (1)
Subadult (25–36 months)		0.1639 \pm 0.15 (1)	
Adult 4–6 (37–60 months)		0.1778 \pm 0.11 (2)	0.0889 \pm 0.08 (1)
Adult 6+ (61–120 months)		0.1607 \pm 0.14 (1)	0.1607 \pm 0.14 (1)
Female total		0.1538 \pm 0.07 (4)	0.1153 \pm 0.06 (3)
Male			
Juvenile (12–24 months)		0.3720 \pm 0.29 (1)	
Subadult (25–36 months)		0.4906 \pm 0.24 (2)	
Adult 4+ (37–120 months)	0.2198 \pm 0.19 (1)	0.4396 \pm 0.23 (2)	
Male total	0.0887 \pm 0.08 (1)	0.4434 \pm 0.14 (5)	
Population total	0.0268 \pm 0.02 (1)	0.2420 \pm 0.07 (9)	0.0806 \pm 0.04 (3)

animals (hunting mortality rate = 0.24; Table 2). Three cougars died of natural causes (natural mortality rate = 0.08), and one adult was killed in a depredation hunt when he was found to be killing domestic sheep (annual depredation mortality rate = 0.02). Four males emigrated and were censored to their last known date in the study area. Three females either shed their collars or went missing after being collared; two adults died during capture and were censored from the data.

Thirty-one cougars were first encountered as kittens (18 were assumed or known to survive to dispersal). Combining high (0.74) and low (0.44) survival estimates for each year produced an annual kitten survival rate of 0.59 ± 0.21 (mean \pm SD). When age classes were pooled for each sex, females had a higher probability of survival than males ($S_F = 0.73$ vs. $S_M = 0.47$, $Z = 1.55$; $df = 1$, $P = 0.06$), mostly the result of higher hunting mortality (female hunting mortality rate = 0.15 vs. male hunting mortality rate = 0.44, $Z = 1.79$; $df = 1$, $P = 0.04$) (Tables 1 and 2).

Maternity and fecundity

Mean maternity was 1.20 kittens per female per year. Annual survival of reproducing-aged females (25+ months) was 0.74 ± 0.09 (mean \pm SD). These combined rates create an annual fecundity rate of 0.45 ± 0.35 for each sex of kitten.

Population growth rates

The deterministic annual growth rate (λ_D) based on our survival and fecundity model was 0.89. The stochastic annual growth rate (λ_S) including the standard deviations of survival and fecundity was 0.84 ± 0.21 (mean \pm SD). The observed growth rate (λ_O) based on the actual number of cougars in the study area was 1.00 ± 0.07 . Both of our modeled growth rates were significantly lower than the observed rate (for λ_D , $t = 2.42$, $df = 2$, $P = 0.07$; for λ_S , $t = 3.68$, $df = 2$, $P = 0.03$).

The observed male component of the population grew at 9% annually, ($\lambda_{OM} = 1.09$), whereas the observed

female component declined at the same rate ($\lambda_{OF} = 0.91$). The observed female growth rate was very similar to the population's deterministic annual growth rate ($\lambda_D = 0.89$).

Population density

Total cougar density averaged 5.03 animals/100 km² and did not change significantly over the study period (see Fig. 3; $F = 0.06$, $P = 0.82$, $R^2 = 0.03$; for all regressions, MS regression $df = 1$; MS residual $df = 2$). Density of adult (>24 months) males appeared to increase, although not significantly, from five individuals in 2001 or 0.68/100 km² to nine individuals in 2005 or 1.22/100 km² ($F = 1.66$, $P = 0.33$, $R^2 = 0.45$), while adult female density remained constant between 13 individuals or 1.77/100 km² and 10 individuals or 1.36/100 km² ($F = 0.71$, $P = 0.49$, $R^2 = 0.26$). The total adult density (males and females >24 months) also remained constant ranging from 17 individuals or 2.32/100 km² in 2001–2002 to 19 individuals or 2.58/100 km² in 2004–2005 ($F = 1.11$, $P = 0.40$, $R^2 = 0.36$).

Age structure

The mean age of the total population was 26 months, adult males 41 months, and adult females 46 months. The average age of independent adult males (>24 months) declined significantly from 47.8 months in 2001 to 36 months in 2005 (see Fig. 4; $F = 37.81$, $P = 0.02$, $R^2 = 0.95$; for all regressions, MS regression $df = 1$; MS residual $df = 2$). The average age of independent females increased, although not significantly, from 42.5 to 54.3 months over the study period ($F = 7.99$, $P = 0.11$, $R^2 = 0.80$).

DISCUSSION

Our closed population survival/fecundity models predicted a rapidly declining cougar population within the study area ($\lambda_D = 0.89$, $\lambda_S = 0.84$), whereas the observed/real population remained stable ($\lambda_O = 1.00$). The real growth rate of 1.00 was significantly higher

FIG. 3. Total and adult cougar (>24 months old) densities (density values given above bars) within the study area in northeastern Washington State, August to August 2001–2005.

than both the modeled deterministic growth rate λ_D and the stochastic growth rate λ_S , the difference representing an 11–16% annual immigration rate. Immigration was also evidenced by no decline in the total or adult population densities, a shift toward males in the adult population (the adult male component of the population was increasing at 9% per year while the female component was declining), and a significant decrease in the average age of independent males. Our results reject the closed-population hunting control hypothesis and support the open-population compensatory/sink immigration hypothesis, which holds that cougar removal in small areas (<1000 km²) will produce high levels of immigration, resulting in little or no reduction in cougar density and a shift in population structure toward younger animals.

The high immigration rates (11–16%), and the disparate growth rates of the male and female components of the population (0.91 female and 1.09 male) suggest that our study area is acting as a sink for the surrounding area. Without immigration of a large number of mostly male cougars, the population would be declining close to the rate predicted by our population models. Immigration into our study area is occurring despite declines in the surrounding area (Fig. 2), due to the intrinsic nature of dispersal in cougar populations.

How far a dispersing animal will travel before establishing a home range is reliant on the quality of

habitat and the number of available mates (Waser 1996:289). Carnivore densities are positively correlated with prey biomass (Hanby et al. 1995, Carbone and Gittleman 2002). High levels of prey availability will cause an increase in the presence of transient or immigrant animals, and may also increase reproduction and survival of neonates and juveniles from within the population (Fuller and Sievert 2001:170). Although male cougars disperse long distances to avoid inbreeding, females disperse to avoid intraspecific competition (Logan and Sweanor 2001:242). As a result, males disperse, on average, twice the distance of females, independent of natal home range density (intrinsic dispersal). High prey availability may be resulting in high immigration of transient animals. We believe that both males and females are immigrating into the study area, although males immigrate on a more constant annual basis, as reflected in the increasing ratio of males to females in the adult population. Data from collared animals suggest that immigrant females have a higher survival rate than males and thus are propagated through the population, whereas males are hunted as juveniles and subadults (Table 2).

Hunting pressure that is not evenly distributed across the landscape has been shown to induce source-sink dynamics in carnivore populations (Doak 1995, Slough and Mowat 1996, Novaro et al. 2005). Hunting is a form of habitat degradation that cannot be perceived by dispersing animals, leading to what Delibes et al. (2001)

FIG. 4. Mean age (values given next to symbols) of the total population, independent adult females (>24 months old), and independent adult males (>24 months old) of a cougar population in northeastern Washington State, 2001–2005 (a solid line denotes a significant [$P < 0.05$] regression for adult males; dashed lines are nonsignificant). Age is based on each animal's average age from August to August of each year.

termed “attractive sinks”; habitat patches of disparate mortality that would otherwise provide abundant resources and high reproduction. When attractive sinks are the preferred habitat, their effect on the greater population is dramatic. The ratio of sink to source habitat sets a threshold above which the total population declines sharply. This threshold is lowered with a decline in sink growth rate. For example, a decline in λ_{sink} from 0.9 to 0.7 results in the lowering of the threshold from 50% to 25% of the greater landscape needing to consist of sink habitat in order for the greater population to decline (Delibes et al. 2001). Depending on other demographic parameters (i.e., initial densities), declines in population may not affect sources and sinks simultaneously. In fact, sink populations may increase while source populations decline (Delibes et al. 2001).

Our study area was a single game management unit (GMU 105, total area 735 km²) within part of the larger Stevens-Pend Orielle cougar management zone (total area 9131 km²) (Fig. 1). Although the harvest quotas are set for the entire management zone, not all areas within that zone are hunted equally due to cougar densities, road access, and snow conditions (Barnhurst 1986, Diefenbach et al. 2004). Total harvest has declined since 2003 in the Stevens-Pend Orielle cougar management zone and earlier (2001) in the greater area (Fig. 2). Although harvest has declined outside the study area, possibly denoting a decline in the greater population (see also Lambert et al. 2006), it has remained constant or increased within the study area while the population has

remained stable. It would appear that metapopulation source-sink population dynamics are functioning within the scale of this single cougar management zone, with some local populations declining while others remain stable. Because males disperse regardless of natal home range density, the surrounding areas need not contain growing or even stable populations to act as a source. An increase in the male cougar population within our study area in response to heavy hunting pressure may be masking a decline in females in the same area and contributing to an overall decline in the greater population. Regardless of the effect on the greater population, it is clear that targeted reductions in small areas will be ineffective as long as habitat quality remains high and source populations exist.

Management implications of carnivore immigration into sink populations

Our findings have two management implications: (1) immigration from neighboring areas may counter management goals of carnivore reduction in small areas, and (2) even within large management zones, population reductions are unlikely to affect the entire region equally, with local immigration possibly masking a declining female population in the target area and an overall decline in the greater area. A similar phenomenon was observed in a heavily hunted brown bear (*Ursus arctos*) population, whereby an apparently increasing population was actually declining toward extirpation (Wielgus and Bunnell 1994).

Making informed management decisions regarding carnivore populations requires that we accurately assess their abundance and population growth rates. Like many other carnivore species, cougar populations are difficult to quantify; therefore, management is often based as much on public perception as on scientifically gathered census data (Minnis 1998). However, the public's perception of wildlife populations often runs counter to that of the scientific community (Freddy et al. 2004). Hunting pressure is often concentrated in areas that have the highest habitat quality and therefore the highest cougar densities. Our findings show that these same areas probably act as sinks, maintaining stable populations through increased immigration from surrounding source areas. If population estimates are based on these heavily hunted sink populations, off-take of recent immigrants could produce the illusion of a growing population in the greater region. However, pre- and post-hunting population densities vary greatly (Anderson and Lindzey 2005) as cougars are quickly replaced by high recruitment. High recruitment, in turn, could lead to public perception of strong population growth and pressure to increase harvest levels. This scenario quickly leads to what Logan and Sweanor (2001:373) describe as the "sledgehammer approach," in which cougar harvest rates are set by crude population indices such as hunter testimony, and populations are well into decline before hunting pressure is reduced.

Targeted reductions of cougar populations in small areas are currently a popular management strategy; however, our data suggest that these reductions may be ineffective if habitat quality remains high or if a source population exists. Reductions employed toward the management goals of reducing predation pressure may be confounded by high recruitment, while cougar-human conflicts may be exacerbated by the influx of younger animals. Ultimately, management aimed at population reduction must address the level of mobility and immigration of the target species. If hunting pressure can be employed uniformly across the landscape, immigration may be lowered by reducing the total population and therefore the number of source populations. This would require much more intense management of carnivores than is presently prescribed by many jurisdictions. Conversely, reducing habitat quality in the smaller targeted area may remove the appeal of an attractive sink, thereby reducing immigration. Sinclair and Krebs (2003) conclude "Food supply is the primary factor determining growth rate in animal populations, and we postulate bottom-up control as the universal primary standard." Others have suggested that prey reduction may provide a viable strategy in carnivore management (e.g., Robinson et al. 2002, Packer et al. 2005). The efficacy of "bottom-up" approaches to cougar management (alternate strategies aimed at reducing prey numbers) remains largely unexplored. We encourage others to study whether such methods may prove viable and appropriate for small management areas.

ACKNOWLEDGMENTS

We thank Tom MacArthur and the venerable Newly and Sooner, without whom this project would have been impossible. Lisa Shipley, Marc Evans, and Kate Odneal provided advice and editorial comments on early versions of the manuscript. John Laundre and an anonymous reviewer provided comments that improved the final version. ABSTRACT Mountain lions (*Puma concolor*) are widely hunted for recreation, population control, and to reduce conflict with humans, but much is still unknown regarding the effects of harvest on mountain lion population dynamics. Whether human hunting mortality on mountain lions is additive or compensatory is debated. Our primary objective was to investigate population effects of harvest on mountain lions. We addressed this objective with a management experiment of 3 years of intensive harvest followed by a 6-year recovery period. In December 2000, after 3 years of hunting, approximately 66% of a single game management unit within the Blackfoot River watershed in Montana was closed to lion hunting, effectively creating a refuge representing approximately 12% (915 km²) of the total study area (7,908 km²). Hunting continued in the remainder of the study area, but harvest levels declined from approximately 9/1,000 km² in 2001 to 2/1,000 km² in 2006 as a result of the protected area and reduced quotas outside. We radiocollared 117 mountain lions from 1998 to 2006. We recorded known fates for 63 animals, and right-censored the remainder. Although hunting directly reduced survival, parameters such as litter size, birth interval, maternity, age at dispersal, and age of first reproduction were not significantly affected. Sensitivity analysis showed that female survival and maternity were most influential on population growth. Life-stage simulation analysis (LSA) demonstrated the effect of hunting on the population dynamics of mountain lions. In our non-hunted population, reproduction (kitten survival and maternity) accounted for approximately 62% of the variation in growth rate, whereas adult female survival accounted for 30%. Hunting reversed this, increasing the reliance of population growth on adult female survival (45% of the variation in population growth), and away from reproduction (12%). Our research showed that harvest at the levels implemented in this study did not affect population productivity (i.e., maternity), but had an additive effect on mountain lion mortality, and therefore population growth. Through harvest, wildlife managers have the ability to control mountain lion populations. Published 2014. This article is a U.S. Government work and is in the public domain in the USA.

KEY WORDS additive mortality, carnivore, compensatory mortality, cougar, hunting, life-stage simulation analysis, Montana, population dynamics, *Puma concolor*, survival.

Errington (1956) coined the term “doomed surplus” to describe animals that would die by other natural causes if not killed by predators. Many hunting programs assume a similar relationship to human harvest, namely, density-dependent compensatory mortality. Modern wildlife management and hunting programs are premised on the idea of sustainable yield, and the concept of a harvestable surplus

due to compensatory mortality (Larkin 1977). Under the compensatory mortality hypothesis, harvest mortalities are compensated by reductions in non-harvest mortality (compensatory mortality), increases in reproduction (compensatory natality), or immigration (Boyce et al. 1999, Williams et al. 2002, Turgeon and Kramer 2012). Evidence of compensation has been shown in a variety of species including game birds (Burnham and Anderson 1984, Sandercock et al. 2011), ungulates (Bartmann et al. 1992, Simard et al. 2013), and carnivores (Sterling et al. 1983, Sparkman et al. 2011). All mortality is not compensatory, however, as evidenced by the numerous populations that

Received: 6 October 2011; Accepted: 16 March 2014

Published: 2 June 2014

¹E-mail: hrobinson@panthera.org

have been threatened or driven to extinction by overharvest (e.g., Baker and Clapham 2004, McGlone 2012). Managers would benefit from a better understanding of the life-history traits and harvest levels where mortality moves from compensatory to additive in many exploited populations (Sandercock et al. 2011, Peron 2013).

Carnivores are hunted for both sport, where population stability is desired, and population control, where mortality must be additive to achieve reduced population levels. In North America, perhaps because of their conflict with humans, a great deal of early research into the effect of harvest on a carnivore species focused on coyotes (*Canis latrans*). This work suggested that harvest mortality was largely compensatory through immigration and density-dependent or compensatory natality (Knowlton 1972, Todd and Keith 1983, Knowlton et al. 1999). These early findings, combined with a reluctance to study other disturbed or hunted populations of large carnivores, shaped management perceptions through the 1970s and 1980s (Frank and Woodroffe 2001). Recent research has suggested that hunting mortality in other carnivores may be almost perfectly additive (Creel and Rotella 2010, Murray et al. 2010).

Evidence of the additive nature of hunting to mountain lion mortality and population growth has been shown in past studies where populations were reduced through hunting, and/or increased once harvest level was reduced (Lindzey et al. 1992, Ross and Jalkotzy 1992, Lambert et al. 2006). Conversely, non-hunted populations often show high levels of intraspecific strife and mortality, leading some to speculate that hunting may be compensatory (Quigley and Hornocker 2010). The effect of harvest on a population is dependent on total harvest rate, age, and sex classes being harvested, and compensation for harvest by increases in survival or other vital rates such as maternity and immigration (Mills 2007).

The combined effects of harvest and dispersal include changes to age and social structure that may cascade through a hunted population, magnifying or reducing the effects of harvest. Mountain lions display high levels of juvenile dispersal (Chepko-Sade et al. 1987, Sweanor et al. 2000, Zimmermann et al. 2005). Males disperse to avoid inbreeding regardless of population density (intrinsic dispersal), whereas females disperse, albeit at much lower levels than males, to avoid intraspecific competition (Greenwood 1980, Logan and Sweanor 2001). Hunting can therefore skew the sex and age ratio of a population towards younger males as harvested males are quickly replaced through juvenile immigration (Robinson et al. 2008). Vertebrate species have adapted to specific age and sex population structures. Males, in general, reach sexual maturity more quickly than females because of reduced life spans (Jones et al. 2008, Ricklefs 2008). Deviations from "natural" population age and demographic structure could reduce productivity (Nussey et al. 2009). Reproductive senescence is common in mammalian females as they age (Packer et al. 1998, Berube et al. 1999). Hostetler et al. (2012) found reduced litter production in female mountain lions (Florida panthers) >9 years. Maternity of

mountain lions may be reduced in hunted populations if younger males do not breed successfully, or if female recruitment is restricted and kitten production is reduced as females senesce (Berube et al. 1999), both additive effects. Conversely, harvest may reduce direct resource competition among females, resulting in increased litter sizes or maternity rates (Ordiz et al. 2008), a compensatory effect.

Logan et al. (1986) and Logan and Sweanor (2001) suggested that removal of male mountain lions from a population may decrease survival of remaining resident males by disrupting social organization and increasing direct or exploitative competition for mates and territory. Also, the loss of dominant, territorial males may increase instances of infanticide, an unexpected additive form of mortality (Logan and Sweanor 2001). Male mountain lions may kill kittens to induce their mothers into estrous, thus increasing breeding opportunities (Packer et al. 2009). However, the role played by infanticide in shaping kitten survival remains unclear. Harvest programs can induce immigration of new males, thereby increasing infanticide rates and limiting population growth (Swenson et al. 1997). A high level of male turnover resulted in increased levels of infanticide in African felids (Whitman et al. 2004, Balme et al. 2010).

Unlike ungulate species that give birth in a single "birth pulse" in early spring, mountain lions give birth year-round. In the United States, mountain lions are most heavily hunted from September to March (Cooléy et al. 2011), which exposes dependent kittens to the risk of starvation due to abandonment following harvest of their mothers, perhaps increasing their naturally high mortality (Logan and Sweanor 2001). Similar to the effects of hunting on adult mortality, however, how this source of mortality is compensated for by decreases in other natural mortality is not well understood.

Ultimately, the compensatory or additive effects of harvest are best measured at the population level in terms of population growth. Matrix population models are a widely used tool for exploring the relationship of various population parameters, or vital rates, on population growth (Getz and Haight 1989, Caswell 2001). Ecologists have used matrix models and the quantifiable properties of sensitivity and elasticity to mathematically describe the consequences of varying vital rates of several species with differing life strategies. Evolutionary theory suggests that natural selection will favor low levels of variation in population parameters that contribute most to population growth (Pfister 1998). In long-lived vertebrates, and other K-selected species, adult female survival normally has the highest demographic elasticity (Gaillard et al. 1998, 2000); that is, small changes in female survival will result in the largest proportional changes in population growth rate.

Although sensitivity analysis will reveal which vital rates have the greatest effect on population growth, those same vital rates may have such low natural variability that they functionally account for little variation in population growth between years. If K-selected species have adapted life strategies where the most important vital rates have the lowest degree of variability, hunting may disrupt this adaptive

Table 1. Predictions of how mountain lion population vital rates should respond to harvest under the compensatory and additive mortality hypothesis.

Vital rate	Compensatory mortality hypothesis	Additive mortality hypothesis
Reproduction		
Litter size	Increase	No effect or reduce
Maternity	Increase	No effect or reduce
Survival	No effect	Reduce
Dispersal		
Male emigration	Reduce	No effect
Female emigration	Reduce	No effect
Male immigration	Increase	No effect
Female immigration	Increase	No effect
Population growth	No effect	Reduce

strategy by increasing their variance. Wisdom et al. (2000) developed an extension of elasticity analysis called life-stage simulation analysis (LSA), which measures the direct effects of annual variance in vital rates on population growth.

We used temporal and spatial variation in harvest structure to test the compensatory mortality hypothesis by directly comparing population parameters (i.e., survival, maternity, etc.), population structure (i.e., mean age of independent males), and population growth between hunted and non-hunted segments of a mountain lion population. Specifically, if harvest mortality was compensatory, we expected population growth to tend toward stability regardless of harvest level because of compensatory reductions in other mortality sources, or through increases in reproduction and recruitment (Table 1). If harvest mortality was additive, we

expected population growth to decline with increased harvest because of reduced survival accompanied by no change in reproduction or recruitment (Table 1). We also used matrix population modeling, sensitivity analysis, and LSA to quantify how harvest affects the natural variability of vital rates, and how those changes are reflected in annual population growth.

STUDY AREA

We conducted the study in the Blackfoot River watershed (7,908 km²) in Powell, Granite, Lewis and Clark, and Missoula counties in West-Central Montana. Hunting district 292 served as our refuge area, hereafter referred to as the Garnet study area (915 km²). This area was protected from hunting for 6 years of the 9-year study (Fig. 1). The entire watershed is characterized by relatively moderate rolling topography, with gentle to moderate slopes dissected by steep limestone canyon areas along drainages (Brainerd 1985). This area is representative of much of western Montana, a mountainous mix of private (i.e., Plum Creek Timber Company and private land owners) and public lands (i.e., Bureau of Land Management, Helena and Lolo National Forests) with elevations ranging from 1,160 m to 2,156 m (Montana Department of Fish, Wildlife and Parks 2004). Daily mean temperatures range from -8.7°C in January to 16.5°C in July with annual precipitation ranging from 19 cm to 33 cm, occurring primarily from December to June (Western Regional Climate Center, Ovando, MT).

Dominant land cover varies from high-elevation mixed lodgepole pine (*Pinus contorta*)-subalpine fir (*Abies lasiocarpa*)

Figure 1. The Garnet study area (915 km²), and greater Blackfoot River watershed (7,908 km²) in western Montana. Numbers (i.e., 292) represent Montana Fish, Wildlife and Parks regional mountain lion management unit designations.

stands, to more mesic Douglas-fir (*Pseudotsuga menziesii*)-western larch (*Larix occidentalis*) stands at mid-elevations, and Douglas fir, ponderosa pine (*P. ponderosa*), and aspen (*Populus tremuloides*) at low elevations. Valley bottoms consist of a mixture of irrigated and dry land agriculture, cattle rangelands, and native bunchgrass-sagebrush (*Artemisia* spp.)-juniper (*Juniperus scopulorum*) communities (Lehmkuhl 1981). The majority of the low to mid-elevation forests have been logged in the past 50 years (Raithel 2005).

Ungulate prey species present in the area included elk (*Cervus elaphus*), white-tailed deer (*Odocoileus virginianus*), mule deer (*Odocoileus hemionus*), and moose (*Alces alces*). Elk populations were stable over the course of the study (Montana Department of Fish, Wildlife and Parks 2004), whereas deer populations may have been recovering from the El Nino-induced severe winter of 1996–1997 (Montana Department of Fish, Wildlife and Parks 2006). Cattle grazing occurred on private and public lands, however, cattle and other livestock depredations by mountain lions were rare. Carnivores besides mountain lions included black bear (*Ursus americanus*) and grizzly bear (*Ursus arctos*). Smaller predators included bobcat (*Lynx rufus*), Canada lynx (*Lynx canadensis*), coyote (*C. latrans*), wolverine (*Gulo gulo*), pine marten (*Martes americana*), and long-tailed weasel (*Mustela frenata*). Wolf (*Canis lupus*) had not recovered during the study period; the first confirmed pack established in 2006, the last year of our study (Montana Department of Fish, Wildlife and Parks 2006).

METHODS

In December 2000, following 3 years of heavy harvest, approximately 66% of a single hunting district was closed to mountain lion hunting, effectively creating a refuge representing approximately 12% (915 km²) of the greater Blackfoot watershed (7,908 km²) in West-Central Montana (Fig. 1). Hunting continued in the remainder of the watershed, but harvest levels declined between 2001 and 2006 as quotas were reduced (Table 2).

Capture and Monitoring

From 1997 to 2000, we applied capture efforts approximately equally across the entire watershed (Fig. 1). Following protection of the Garnet study area, we focused most capture efforts there, towards the goal of capturing all resident individuals (i.e., census). In the remainder of the Blackfoot,

we continued to monitor radioed lions marked during the first 3 years of the study including re-instrumenting individuals when their radiocollar's battery life was spent. In addition, we monitored animals that either dispersed from the Garnet or had home ranges overlapping the boundary between the 2 areas.

We used trained hounds to tree mountain lions when we located fresh tracks in the snow. We darted treed animals and drugged them with a 0.06 ml/kg estimated weight mixture of ketamine hydrochloride and xylazine hydrochloride (1.45 ml xylazine to 10 ml ketamine) delivered using a Pneu-Dart Model 193SS cartridge fired rifle with disposable darts (Pneu-Dart, Inc., Williamsport, PA). We gave animals the antagonist yohimbine hydrochloride to counteract the xylazine before release.

We estimated age of captured mountain lions by tooth replacement, wear, gum recession, and cementum age analysis (Ashman et al. 1983, Laundre et al. 2000). We fitted radiocollars (Telonics, Mesa, AZ) depending on the size and age of the individual: an expandable (20–34 cm) kitten collar equipped with either a Mod-073 or Mod-305 transmitter, or an adult collar equipped with a Mod-500 transmitter. We located collared animals from fixed-wing aircraft approximately twice per week. Beginning in 2001, we fitted Telonics global positioning system (GPS) collars programmed to acquire a location every 5 hours to newly collared animals and replaced very high frequency (VHF) collars on already marked animals as opportunity allowed.

We collared both newborn kittens at the den, and those traveling with newly collared adult females. We collared newborn kittens without chemical immobilization approximately 1 month from the time the mother localized at a den site. When we located kittens outside the den (from 3 to 12 months) we treed and immobilized them as with adults. Expandable Mod-073 collars remained on kittens up to 7 months of age; mod-305 collars remained on kittens up to 10 months of age; and a mod-500 adult collar was worn by the animal through adulthood. Capture and handling protocols were approved by Montana Fish, Wildlife and Parks and conducted by their staff (Montana Department of Fish, Wildlife and Parks 2007).

Population Characteristics

Sex and age structure.—We calculated a minimum population for the Garnet study area each year by back-

Table 2. Mountain lion harvest, quotas (harvest/quota), and harvest density (animals/1,000 km²) for the Blackfoot River watershed in West-Central Montana, 1998–2006. Beginning in December 2000, the Garnet was managed separately from the remainder of the Blackfoot watershed.

Area	Sex	1998	1999	2000	2001	2002	2003	2004	2005	2006
Garnet	Female	8 ^a	8 ^a	8 ^a	0	0	0	0/1 ^b	0	0
	Harvest density	8.74	8.74	8.74						
	Male	5 ^a	6 ^a	6 ^a	0	0	0	1/1 ^b	1/1	1/1
	Harvest density	5.46	6.55	6.55				1.09	1.09	1.09
Black-foot	Female	35/30	42/41	30/30	15/15	10/9	4/3	4/3	0/0	1/0
	Harvest density	4.42	5.31	3.79	1.89	1.26	0.5	0.5	0	0.12
	Male	41/40	30/33	27/29	19/21	12/9	8/7	7/7	6/7	8/7
	Harvest density	9.61	9.10	7.20	4.29	2.78	1.51	1.39	0.75	1.13

calculating the lifespan of all mountain lions known to have been present in the study area including collared and harvested animals (Logan and Sweanor 2001, Stoner et al. 2006, Robinson et al. 2008). This technique assumes that animals collared or harvested without being collared at time t were present within the watershed but undetected at time $t - 1$ (specific to each animal's age and sex); as such, this method may underestimate population levels towards the end of the study period because of fewer sampling occasions. We assumed that all males were immigrants, whereas all females were recruited from within the population. Therefore, we backdated males to 24 months of age, immigrating into the population after their second birthday. We assumed females were philopatric and were likely born inside the Blackfoot watershed; however, we could not be sure if they were born inside or outside the protected Garnet study area. Therefore, we backdated females to 12 months, accounting for our philopatric assumption without biasing further any total population estimate of the Garnet study area. We used a Z-test to compare mean ages and proportion of the population consisting of adults of each sex between the hunted and non-hunted populations (Zar 1999). We hypothesized that harvest would reduce the mean age of males while increasing their proportion in the population because of a compensatory immigration response to harvest, whereas harvest would increase the mean age of adult females in the population while reducing their proportion in the population because of reduced recruitment (i.e., high juvenile mortality and/or low immigration) as resident animals aged.

Reproduction.—We estimated maternity, the mean number of young born per reproductive female per year (Caswell 2001), and its component, litter size, based on females of reproductive age within the Garnet study area only. We felt monitoring effort was sufficient within the Garnet that no litters born to, or traveling with, collared females would be missed, but logistical constraints prevented this level of monitoring in the larger watershed. We estimated average litter size based on kittens observed at den sites (i.e., <7 weeks), which assumes no kitten mortality had occurred prior to observation. The compensatory mortality hypothesis predicts that litter size will increase in a hunted population because of increased available resources (Table 1). The additive mortality hypothesis predicts that litter size will be unaffected or decline with harvest because of the age structure of females (Table 1). We tested the effect of harvest on litter size (as observed at den sites when kittens were <7 weeks) using a repeated-measures analysis of variance (ANOVA) comparing litter size within the Garnet study area during hunting and non-hunting periods. We used a repeated-measures ANOVA as the sample consisted of females with multiple litters (Zar 1999).

We observed age at dispersal and, for animals that did not leave the study area, first reproduction by radiocollaring dependent kittens and juveniles. As some hunted populations have a population skewed towards older females, we also tested how or if female age affected litter size. Using a repeated-measures ANOVA, we tested for an age effect on litter size in the females that we monitored (Zar 1999).

Reduced fertility in older females could be an additive effect of harvest (Table 1).

Some researchers have used litter size, mean birth interval, and proportion of females traveling with young as surrogate measures of maternity (e.g., Lambert et al. 2006); however, these measures may introduce a bias by excluding females that fail to reproduce. We estimated maternity rate based on the total number of kittens born to all radiocollared females of reproductive age (>24 months) monitored, thus including the proportion of non-reproductive females in the population. As with litter size, the compensatory mortality hypothesis predicts that maternity rate will increase in the hunted population because of reduced competition and increased resource availability, whereas the additive mortality hypothesis predicts that maternity will be reduced or unchanged between hunted and non-hunted periods (Table 1). We tested for a hunting effect on maternity rate using a Z-test to compare the mean annual maternity rate within the Garnet study area during hunting and following protection (Zar 1999).

Dispersal.—We defined dispersal as a juvenile establishing a home range with <5% overlap of its natal home range, whereas we considered juveniles establishing home ranges with >5% overlap to be philopatric (Logan and Sweanor 2001). Dispersal rate was based on the number of independent juveniles in each year that moved outside their natal home range compared to the number monitored. We modeled juvenile dispersal as a binomial function of the estimated total population size for males and females separately (i.e., we used a generalized linear model specifying a logit link and binomial family; Hardin and Hilbe 2007). The additive mortality hypothesis predicts density-independent dispersal, whereas the compensatory mortality hypothesis suggests reduced dispersal of both sexes in the hunted population (Table 1).

Survival and Mortality

We examined mountain lion mortality in 3 ways: survival modeling, survival rate analysis, and cause-specific mortality analysis. We used survival modeling to examine the effect of independent variables (i.e., sex, age, geographic location, and hunting pressure as dictated by quota levels) on mountain lion survival and to objectively determine the best method of breaking the population into segments or cohorts with similar survival experiences. We used survival analysis to calculate and compare the survival probabilities of animals within those cohorts. Finally, we calculated and compared cause-specific mortality rates.

We derived a spatially explicit encounter history from telemetry data for each individual mountain lion to estimate survival rates and test hypotheses about factors influencing survival. We removed duplicate same-day locations from GPS collar data and combined them with VHF data to create a continuous record based on calendar time for each animal (Fieberg and DelGiudice 2009). We censored (interval truncated) animals not located for >61 days until relocated (Winterstein et al. 2001). During the first 4 years of the study, before we began to deploy GPS collars, we scheduled

telemetry flights twice a week. During some periods, most notably the winter and spring of 2001, we could conduct flights only once a month because of weather, financial, and logistical constraints. We began deploying GPS collars in October 2001 and aerial telemetry flights were again limited during short periods for the remainder of the study. The 61-day period allowed some animals to be missed on 2 consecutive flights during these times of infrequent aerial telemetry. If not located after 61 days, we right-censored animals at the date of their last location in the study area.

We modeled factors influencing mountain lion survival using a combination of manual backward stepwise and best-subsets model selection (Hosmer et al. 2008). First, we conducted a univariate analysis using Cox regression (Cox 1972) to test the significance of sex, age, and hunting quota on mountain lion survival. We coded sex as an indicator variable with females coded as 1 and males coded as 0. We coded age and quota level as continuous variables, with age estimated in months and quota based on the annual-, sex-, and location-specific quotas as set by Montana Fish, Wildlife and Parks (Table 2).

We modeled mountain lion survival on the landscape by constructing 12 spatiotemporal *a priori* models, each suggesting a different hypothesized response in survival of the population to our experimental harvest design. We discuss 4 of these models in detail here (see online Supplementary Material for graphical depiction and explanation of all 12). For instance, the single-population (1-segment) model tested the hypothesis of total compensatory mortality by modeling survival as constant across the landscape and study period; equivalent to a null model relative to management (Fig. S1). The other 3 models represented different ways in which hunting mortality might be manifest. The management model tested the hypothesis that survival responded to small incremental changes in management or quota level, thus dividing the population into 6 segments, equivalent to a global model relative to management (Fig. S2, see also Table 2). The 3-segment population model grouped animals across the drainage between 1998 and 2000 (segment 1), then divided the population into 2 segments (segments 2 and 3) based on the protection of the Garnet study area following 2000, while hunting continued in the remainder of the Blackfoot drainage (Fig. S3). Under the compensatory mortality hypothesis, hunting replaces other forms of mortality, causing survival to remain relatively constant. Therefore, this model would not be supported if the compensatory hypothesis were true because survival between segments 2 and 3 would not differ. The 4-segment model (Fig. S4) tested the hypothesis that survival before protection of the Garnet study area differed between the watershed and the Garnet although management was the same for both areas, and that survival increased significantly outside the protected area once female quotas were set to 0. We used Akaike's Information Criterion for small sample sizes (AIC_c) to select among competing models to evaluate the strength of evidence for each hypothesis regarding the relationship of survival to temporal and geographical quota levels, as well as

age and sex (Burnham and Anderson 1998, Hosmer et al. 2008).

We modeled survival time using a parametric Weibull distribution (Hosmer et al. 2008):

$$\ln(T) = \beta_0 + \beta_1 x + \sigma \times \varepsilon \quad (1)$$

where T is survival time, β_0 the model intercept, β_1 the covariate, σ a parameter estimating the shape of the hazard function based on the data, and ε the error term. We checked model specification using a link test (Cleves et al. 2004).

We calculated annual survival rates for 3 age classes of mountain lions: kitten (1–12 months), juvenile (13–24 months), and adult (>25 months) for each population model segment (as delineated by our *a priori* model selection, see above) using the Nelson–Aalen estimator (Nelson 1972, Aalen 1978). Because kittens were first collared at a range of ages (1–12 months) rather than only at the den (i.e., within the first 7 weeks), our estimate of kitten survival is biased high. We based survival rates on a biological year (1 Dec–30 Nov) reflecting the start of the hound-hunting season on 1 December. We raised the cumulative hazard estimate for each segment to the power of $1/t$, where t represents the length of that period in years, to calculate a mean annual survival rate across that period. To test for differences in survival between the various segments of the population, we used a Peto–Prentice test (Peto and Peto 1972, Prentice 1978, Hosmer et al. 2008). The compensatory mortality hypothesis predicts no difference in survival between hunted and non-hunted segments of the population. Conversely, reduced survival in the hunted population would indicate additive mortality.

We calculated cause-specific mortality rates using cumulative incidence functions (CIFs; Kalbfleisch and Prentice 1980, Heisey and Patterson 2006). These functions allow the estimation of mortality rates in the presence of competing risks, which are defined as >1 mutually exclusive, cause of death (Pintilie 2006). Unlike the modified Mayfield or Heisey–Fuller (Mayfield 1961, Heisey and Fuller 1985) methods of mortality estimation, which assume a normal or constant distribution of mortality risk, CIFs are non-parametric and make no assumption regarding the underlying hazard distribution.

We grouped mortalities by 6 causes. We classified animals that were harvested as part of a legal hunt, or kittens that were orphaned and starved after their mothers were shot as hunting mortality. Illegal mortality included animals killed in snares or otherwise killed out of season. We classified animals that died naturally because of starvation, disease, or intraspecific strife (including cases of infanticide) as natural mortalities. The category depredation included animals shot because of conflict with humans (i.e., livestock depredation permits, and self-defense). The final 2 categories were vehicle collisions and unknown, where a clear cause of death could not be determined.

We used cause-specific mortality rates to test the compensatory mortality hypothesis in 2 ways. First, we regressed survival of juvenile and adult mountain lions against hunting mortality. We omitted kittens because of

their non-independence from adult females. We included juveniles because they spend approximately half of their juvenile year independent of their mothers and, unlike kittens, no juveniles starved after being orphaned by hunting. If hunting were compensatory, we would expect survival to remain constant as hunting mortality increased (Table 1). Conversely if hunting mortality were additive, we would expect a monotonic decrease in survival with an increase in hunting mortality (Williams et al. 2002). This regression used survival and hunting mortality probabilities based on the management model population structure (i.e., 6 population segments based on varying hunting quota levels, see Fig. S2). A similar analysis could have been conducted on annual survival and mortality values (e.g., Murray et al. 2010). However, because the management goal during the first 3 years of the study was to reduce the population, almost ensuring additive mortality, using annual rates may have biased our analysis towards inferring additivity of hunting mortality. We assumed this structure was less biased than an annual model towards an additive finding because the first 3 years of mortality are captured in a single data point and the model contains both hunting and natural mortality based on the protected and hunted portions of the Blackfoot watershed following December 2000.

We also tested the compensatory mortality hypothesis in adult and kitten survival by comparing the CIF for hunting and all other mortality sources between the hunted and non-hunted periods. Pepe and Mori (1993) provided a method for comparing the CIF of a main mortality source and competing risks simultaneously between 2 groups. This method tests the hypothesis of equality in the CIF of a main event (i.e., hunting mortality) while also testing for equality in the remaining competing risks (Pintilie 2006). If hunting mortality were additive, we would expect an increase in the hunting mortality rate, whereas the CIF for competing risks would be constant (i.e., no compensatory decrease in other mortality sources in the presence of hunting). Conversely, if hunting mortality were compensatory, we would expect an increase in the hunting CIF, with a concurrent reduction in the CIF for competing risks in the hunted population.

Population Modeling and Growth

Methods described thus far examined how harvest affected individual population parameters (i.e., survival, maternity, etc.). Ultimately, we were interested in how changes in these parameters combined to affect population growth. To quantify the population effects of harvest, we constructed a stage-based, 2-site, dual-sex Leslie matrix model (Leslie 1945) in MATLAB[®] (The MathWorks, Natick, MA). The model consisted of 2 transition matrices joined by juvenile dispersal terms and was based on the 2 top survival models using the estimated survival and fecundity parameters described below. We calculated stochastic growth rates and associated standard deviations by running 10,000 2- to 6-year iterations (dependent on population segment, see Supplementary Material).

Vital rates.—We used age- and sex-specific survival rates previously discussed, estimated using the Nelson–Aalen

estimator. We estimated variance of the Nelson–Aalen survival estimator following Anderson et al. (1997):

$$\text{Var}(\hat{S}(t)) = (\hat{S}(t))^2 V^2(t) \quad (2)$$

and

$$V^2(t) = \sum_{(i:t_i < t)} \frac{d_i(r_i - d_i)}{r_i^3} \quad (3)$$

where $\hat{S}(t)$ is the survival estimate to time t , d_i is the number of deaths at time t_i , and r is the number at risk at time t_i . We then used White's method to remove sampling variance from annual estimations of survival variance, and included this value of process variance in a beta-distributed variance vector in each matrix model (White 2000).

We assumed that females did not breed until becoming adults (>24 months; Root 2004, Robinson et al. 2008, Treves 2009). We also assumed an equal ratio of male and female kittens (total fecundity divided equally between sexes; Logan and Sweanor 2001). We modeled variance in maternity using a stretched beta distribution with a maximum value of 2.5 annually, or maximum litter size of 5 every 2 years (Morris and Doak 2002). We modeled fecundity as a birth-pulse post-breeding process. Kittens entered the matrix as newborns and fecundity was the product of adult female survival (S_a) and average annual maternity (M_a ; Morris and Doak 2002):

$$F = S_a \times M_a \quad (4)$$

We calculated a dispersal rate based on the number of independent juveniles in each year that moved between the Garnet study area and the remainder of the Blackfoot drainage compared to the number monitored. In this sense, our modeling definition of dispersal does not match the more traditional definition (reported above), where juveniles that establish home ranges with >5% overlap of their maternal home range are considered to be philopatric rather than dispersers (Logan and Sweanor 2001). Our model assumed a closed system consisting only of 2 populations, the Garnet study area and the remainder of the Blackfoot watershed. Therefore, for parameterization of our population models, an animal could have established a home range adjacent or overlapping with its mother's (philopatry) but still be classified as a disperser if its new home range was primarily (>50%) outside its maternal area (the Garnet area or the remainder of the drainage). We did not consider juveniles that dispersed out of the Blackfoot watershed completely to be dispersers because they were effectively lost to this system and population model and we therefore censored them.

Initial abundance and density dependence.—We set initial 1998 abundances at 37 total animals (i.e., kittens, juveniles, and adults) for the Garnet study area based on a minimum population back-calculated using known-aged animals, and 283 total individuals in the remainder of the Blackfoot drainage, extrapolating a similar total density (4.0 mountain lions/100 km²) to the remainder of the watershed. We started all models in 1998 at a stable age distribution, then the mean modeled age distribution for further projections.

For instance, we started the 3-segment population model in 1998 with a stable age distribution and projected for 3 years, when survival rates changed or diverged between the Garnet and remainder of the Blackfoot. We projected a second period from 2001 to 2007 based on the age distribution outputs from the 1998 to 2000 model.

We applied a ceiling density dependence to stochastic models that affected survival of adults only (>24 months; Root 2004). We set a ceiling density of 27 adults for the Garnet study area and 210 adults for the remainder of the Blackfoot drainage based on an average density of 3 adults per 100 km². This liberal estimate of maximum adult density was commensurate with observed levels of 2.92 mountain lions/100 km² in Wyoming (Anderson and Lindzey 2005) and 2.58 mountain lions/100 km² in northeastern Washington (Robinson et al. 2008) both hunted populations.

Sensitivity and life-stage simulation analysis.—If harvest is additive, its effect on total population growth should vary based on which population parameter is affected in an additive manner and how reliant population growth is on that parameter. We tested the effect of each population parameter on population growth rate through perturbation. The sensitivity of lambda to each vital rate (i.e., survival, maternity, and dispersal) was calculated by individually reducing each rate by 0.10 and recalculating lambda for each population as well as the total population combined (Caswell 2001). The inclusion of lower-level parameters (maternity and female survival combined to calculate fecundity) in our matrix model negated the use of elasticities (Caswell 2001). We conducted an LSA to quantify the effects of variance on population growth within the Garnet study area separately during the hunted period (1998–2000), and the non-hunted period (2001–2006), comparing the r^2 values for each vital rate, for each period (Wisdom et al. 2000). We conducted sensitivity analysis using the 3-segment population model. Because we were only interested in the effect of harvest on vital rate variability and population growth, we conducted LSA on only the Garnet portion of the 3-segment population model pre- and post-harvest (i.e., segment 1 vs. segment 2, see Fig. S3).

Finally, given the results of our sensitivity and LSA analysis, we constructed a deterministic population model to quantify how varying levels of maternity, female kitten survival, and adult female survival combine to affect population growth. In this model, we fixed all male survival rates as well as juvenile female survival at the average levels observed for the entire study population, but ran successive simulations in which we incrementally increased kitten and adult female survival from 0.01 to 1.0, at 3 levels of maternity (1.08, 1.29, and 1.40; maternity during the hunting period, mean maternity across the study period, and maternity during the non-hunting period, respectively). We used standard matrix analysis techniques (Caswell 2001) to calculate the projected long-term population growth rate (λ) for each possible parameter combination. The probability of a kitten surviving to become a juvenile was the combined function of kitten and adult survival (i.e., kitten survival \times adult survival) to mimic the effect of kitten abandonment

following an adult's death. We modeled fecundity levels as in the other population models.

RESULTS

Harvest, Capture, and Monitoring

From 1998 to 2006, 299 mountain lions (158 M and 141 F) were harvested from the Blackfoot watershed, with 41 (18 M, 23 F) harvested from the Garnet study area. Mean age of harvested animals was 2.88 years ($M \bar{x} = 2.64$ yr and $F \bar{x} = 3.16$ yr). A female quota existed in all but the last 2 years of the study in the Blackfoot watershed. This quota was filled or exceeded in each year (i.e., 100–133% quota), and females composed 37% of the animals harvested (Table 2).

We captured 121 individual mountain lions 152 times between January 1998 and December 2006, including 82 kittens, 8 juveniles, and 31 adults. Of these, we collared 117 individuals and monitored them for habitat use and survival. We monitored animals for an average of 502 days (range: 7–3,231 days) with males remaining on the air for shorter periods ($\bar{x} = 284$ days) than females ($\bar{x} = 658$ days). We recorded known fates for 63 animals, and right-censored the remainder. We used right-censored animals in analysis until loss due to collar failure ($n = 16$), dispersal from the Blackfoot River drainage ($n = 7$), or survival to the end of the study ($n = 31$).

Population Characteristics

Sex and age structure.—The minimum total population count for the Garnet study area ranged from 37 mountain lions (4.0/100 km²) in 1997 to a low of 20 (2.2/100 km²) in 1999, before recovering to 33 (3.6/100 km²) in 2006 (Table 3). The average age of adult females increased from 3.53 years during the hunted period to 4.83 in the non-hunted population, although this difference was not significant ($Z = -1.47$, $P = 0.14$). Similarly, the average age of adult males increased from 2.73 to 3.53, also a non-significant increase ($Z = -1.46$, $P = 0.14$). The oldest radiocollared female monitored during the study was 10 years old and the oldest male was 6 years old.

From 1997 to 2006, the Garnet population averaged 37% adult females, 15% adult males, 17% juveniles, and 30% kittens. Although the proportion of adult females in the population remained relatively constant between the hunted and non-hunted phases ($Z = 1.20$, $P = 0.22$), the proportion of adult males in the hunted population was higher (21%) than in the non-hunted (10%; $Z = 2.87$, $P < 0.01$; Table 3.).

Reproduction.—Mean total litter size of litters visited early in the den (<7 weeks) was 2.92 ($n = 24$, 95% CI: 2.70–3.13). Litter size was not affected by hunting ($F_{1,11} = 0.27$, $P = 0.61$). Of 32 litters where birth month could be confirmed, mountain lions gave birth in all months but December, February, and March. Most litters were produced from July to October. The mean age of sires in our population was 35 months (Onorato et al. 2011). Fourteen known-aged females gave birth to their first litter at a mean age of 31.4 months (range: 23–37 months). We found no effect of female age on litter size ($F_{6,6} = 1.39$, $P = 0.35$). Average birth interval was 602.6 days (95% CI: 503–702

Table 3. Minimum total mountain lion population (including kittens, juveniles, and adults), mean adult age, and proportion of total population consisting of adult male and female mountain lions censused on 1 December, 1997–2006, Garnet study area, western Montana.

Year	Minimum total population	Mean adult age (yr)		Adult proportion of total population	
		Male	Female	Male	Female
1997	37	2.29	3.79	0.189	0.378
1998	27	2.83	3.91	0.222	0.407
1999	20	2.8	3.7	0.25	0.5
2000	21	3	2.75	0.19	0.381
Hunted mean		2.73	3.53	0.21	0.42
2001	25	3.67	3.75	0.12	0.32
2002	24	3	4.44	0.125	0.375
2003	30	4	4.82	0.1	0.367
2004	32	3	4.91	0.094	0.344
2005	33	3.5	5.27	0.121	0.333
2006	33	4	5.8	0.061	0.303
Non-hunted mean		3.53	4.83	0.10	0.34

days) or 19.8 months. Approximately 58% of females ≥ 24 months gave birth each year, and 89% of females were traveling with dependent young.

The mean maternity rate across the study period was 1.29 ($n=9$, 95% CI: 0.84–1.76) kittens per female per year. Although maternity was lower during the hunting period ($\bar{x}=1.08$, $n=3$, 95% CI: 0–3.59) compared to the protected population ($\bar{x}=1.40$, $n=6$, 95% CI: 1.02–1.78), this difference was not significant ($Z=-0.53$, $P=0.59$). In 1999, we documented no litters born to collared females; however, because of heavy harvest pressure, we monitored only 2 adult females.

Dispersal.—We monitored 66 mountain lions (39 F and 27 M) during their juvenile year (13–24 months of age) during 1998–2006. Of these 66 individuals, 47 survived to independence. Mean age of dispersal was 15 months ($n=33$, range: 11–23 months). Dispersal was severely constrained in the hunted population before 2001. During the first 3 years of study when harvest level was high, only 2 of 12 juvenile females survived to independence. One dispersed out of the Blackfoot drainage, and 1 established a philopatric home range inside the Garnet study area. Between 2001 and 2006, during protection of the Garnet from hunting, we monitored 54 juvenile mountain lions, 45 of which survived to independence. In total, female juveniles showed essentially equal levels of dispersal ($n=12$) and philopatric behavior ($n=14$). We found no relationship between population level and dispersal rate of juvenile females ($Z_5=0.60$, $P=0.55$). We did not document any philopatric behavior in radiocollared juvenile males ($n=19$; 100% dispersal).

Survival and Mortality

We recorded mortalities in every month but October, with the majority coinciding with the start of the hound-hunting season in December (Fig. 2). Sex was the best predictor of mountain lion survival followed by quota and age. Females were 73% less likely than males to die (hazard ratio [HR]=0.27, $Z=-4.79$, $P<0.01$), with risk of mortality increasing 10% with each numerical increase in quotas (HR=1.10, $Z=2.77$, $P<0.01$). Risk of mortality was highest for kittens, declining by 1% for each month survived

(HR=0.99, $Z=-1.52$, $P=0.11$). Although age was not a significant model covariate at the 0.05 level, Hosmer and Lemeshow (2000) recommend retaining variables with a probability of significance of 20% ($P=0.2$) for inclusion in further modeling following univariate analysis. This recommendation, coupled with our desire to create age-based population models as the next phase of our research, led to inclusion of all 3 variables in our subset models, with age broken into 3 categories.

Two models, 3-segment and 4-segment, including 3 age classes and sex, were the top models (Table 4; Figs. S3 and S4). The management model, which we thought best fit the actual quota levels, was the seventh ranked model (Table 4). A linktest showed that both the 3-segment ($Z=-0.51$, $P=0.61$) and the 4-segment ($Z=-0.58$, $P=0.56$) models were properly parameterized.

Mean annual survival, pooling all individuals across all years, was 0.651 (SD=0.03). Survival of kittens ($\bar{x}=0.785$, SD=0.05) and juveniles ($\bar{x}=0.592$, SD=0.09) did not vary by sex (kitten: $\chi^2_1=0.14$, $P=0.70$; juvenile: $\chi^2_1=0.18$, $P=0.66$). Among adults, female survival ($\bar{x}=0.786$,

Table 4. Top models in best-fit analysis of mountain lion survival patterns in Blackfoot watershed Montana, 1998–2006. Null model log likelihood (LL) was –54.2168 (8 remaining models in Table S1).

Rank	Model	LL	df	AIC _c	ΔAIC _c
1	3-Segment	–36.1078	7	87.1115	0
2	4-Segment	–35.5328	8	88.2269	1.1154
7	Management	–35.4528	10	92.7088	5.5973
10	1-Segment	–44.1786	5	98.8296	11.7181

SD = 0.05) was higher than males (\bar{x} = 0.515, SD = 0.12; χ^2_1 = 5.04, P = 0.02).

Adult survival (F: n = 13, M: n = 3) was similar between the Garnet study area and the remainder of the Blackfoot drainage before December 2000 (χ^2_1 = 0.45, P = 0.50), but differed once hunting was halted in the Garnet (χ^2_1 = 17.62, P < 0.01; F: n = 38, M: n = 17; Table 5), consistent with the additive mortality hypothesis. Once adult female quotas were reduced to 0 outside the Garnet study area (segment 4 of the 4-segment population model, see Fig. S4), adult survival increased from 0.60 to 0.87 (χ^2_1 = 3.08, P = 0.08) compared to survival before quota reduction (population segment 2). The marginal significance in total adult survival is explained by an increase in adult female survival while adult male survival remained relatively constant (Table 5).

Hunting was the main cause of mortality for all age and sex classes across the study period, accounting for 36 of 63 mortalities documented. Additional factors were illegal mortalities, natural, unknown, depredation, and vehicle collision (Table 6). Across the study period, mountain lions in the Blackfoot watershed had a 22% annual probability of mortality due to hunting. Regression analysis of hunting-caused mortality and survival of juveniles and adults showed a significant negative slope of –0.97 ($F_{1,4}$ = 21.97, P = 0.01), consistent with the additive-hunting mortality hypothesis and suggesting hunting mortality is completely additive (Fig. 3). For adults and juveniles, PepeMori tests of equality in cause-specific mortality rates were significant (hunting mortality χ^2 = 31.18, P < 0.01; all other mortality χ^2 = 3.58, P = 0.06). The difference in other mortality sources between hunted and non-hunted populations was due to higher mortality in the hunted populations, supporting the additive-hunting mortality hypothesis.

During the heavy hunting period before closure of the Garnet study area, 6 kittens died of starvation following the harvest of their mothers, leading to a kitten cause-specific mortality rate of 0.41 (SE = 0.14). During the same period, no kittens died of natural mortality; however, following closure of the Garnet study area, 6 kittens died of natural causes including cannibalism or infanticide, a cause-specific mortality rate of 0.16 (SE = 0.06). Kitten mortality

Table 5. Mean annual survival rates of radiocollared mountain lions broken into population segments according to our 3- and 4-segment model structures 1998–2006, western Montana. Sample sizes (n) include animals that were counted in the risk pool of more than 1 model segment. The 3-segment model assumes that survival was similar across the watershed prior to protection of the Garnet (combined hunted), but differed after December 2000 when hunting ceased in the Garnet (Garnet protected and Blackfoot hunted). The 4-segment model assumes survival differed among 4 groups: 1) Garnet study area before December 2000 (Garnet hunted), 2) Garnet study area after hunting ceased in the area (Garnet protected), 3) Blackfoot watershed before 2005 (Blackfoot hunted), and 4) Blackfoot watershed during the last 2 years of the study when female quotas were reduced to 0 (Blackfoot hunted reduced). Survival of kittens and juveniles did not vary by sex; therefore, we present pooled estimates.

Model and segment	Area (yr)	Age and sex	n	Mean survival	SD
3-segment 1	Combined hunted (1998–2000)	Kitten	24	0.6566	0.09
		Juvenile	12	0.3117	0.12

attributed to hunting was higher during the 3-year period of heavy hunting than in the 6 years following protection of the Garnet study area ($\chi^2 = 7.58$, $P = 0.01$). However, we found no change in all other sources of mortality between the 2 periods ($\chi^2 = 0.49$, $P = 0.48$), supporting the additive mortality hypothesis.

Population Modeling and Growth

We monitored 47 kittens until independence from their mothers. One female and 6 males dispersed out of the watershed completely and were censored from dispersal rate calculations. Dispersal rates of juveniles from the Garnet study area to the Blackfoot was 0 prior to the cessation of hunting, but increased to 0.82 ± 0.19 per year for females and 0.71 ± 0.39 per year for males once the Garnet was closed to hunting. No radiocollared juveniles immigrated into the Garnet study area from the remainder of the Blackfoot watershed, where hunting was allowed, although low juvenile survival reduced the number of independent juveniles in our Blackfoot sample to 4 (3 F and 1 M), all of which remained in the hunted area.

Our population models indicated that the mountain lion population in the Blackfoot watershed declined by approximately 11–12% per year between 1998 and 2000 (Table 7). With cessation of hunting in the Garnet study area in 2001, the 3-segment model predicted recovery beginning immedi-

ately, with the watershed population growing at approximately 3% annually (Table 7). The 4-segment model indicated that mountain lion numbers in the watershed were still slightly declining between 2001 and 2004, before climbing rapidly following reductions in quotas outside the Garnet in 2005 (Table 7). Both models predicted a watershed-wide population level in January 2007 slightly below 1998 levels (Fig. 4). Both models also predicted final abundances in the Garnet study area of approximately 28 individuals, 9 fewer than at the start of the study. The trend in watershed-wide estimates from both modeled populations matches the minimum count for the Garnet based on backdating (Fig. 4); however, both models predicted a slower recovery within the Garnet study area than the minimum count for the number of animals based on backdating (Fig. 4).

The growth rate of the watershed-wide, mountain lion population was most sensitive to changes in adult female survival followed by juvenile and kitten female survival and maternity (Fig. 5). Negative sensitivities of dispersal from the Garnet to the hunted area of the watershed following 2001 attest to the lower survival probability of adults in the hunted area compared to the protected Garnet. LSA showed that hunting increased the importance of adult female survival to population growth by 50%, while reducing the significance of kitten survival and maternity (Fig. 6). The sum of adult female survival, female kitten survival, and maternity accounted for 92% and 57% of the variability in annual population growth of non-hunted and hunted populations, respectively. In general, adult female survival levels below 0.80 should lead to declining population levels (Fig. 7).

DISCUSSION

Population Characteristics

Hunting directly reduced population size from 37 to 20 animals between 1997 and 2000, but population parameters such as litter size, birth interval, maternity, age at dispersal, and age at first breeding were not significantly affected. Increased harvest increased the proportion of adult males in the population, while reducing the average age of both adult males and females, likely because of a compensatory immigration response into vacated home ranges (Cooley et al. 2009). We had hypothesized that female recruitment would be reduced by harvest, perhaps more greatly than

Figure 3. Regression of the relationship of hunting mortality and survival of independent mountain lions, 1998–2006, in the Blackfoot River watershed, Montana based on the management model population breakdown (see also Fig. S2).

Table 7. Modeled population growth rate (λ ; \pm SD) based on the 3- and 4-segment population models in western Montana, 1998–2006.

Study area	Model	1998–2000 (λ)	2001–2004 (λ)	2005–2006 (λ)
Garnet	3-Segment	0.8686 (0.08)	1.024 (0.06)	1.024 (0.06)
	4-Segment	0.9352 (0.11)	0.9855 (0.05)	1.016 (0.09)
Blackfoot	3-Segment	0.8797 (0.08)	1.033 (0.06)	1.033 (0.06)
	4-Segment	0.8829 (0.12)	0.9375 (0.11)	1.176 (0.10)
Combined	3-Segment	0.8795 (0.08)	1.034 (0.05)	1.034 (0.05)
	4-Segment	0.8928 (0.11)	0.9475 (0.09)	1.155 (0.09)

males because of shorter female dispersal distance and reduced juvenile survival, resulting in an increased adult female age structure. Both female and male immigration were likely occurring during the heavy harvest period despite very low juvenile survival in the study area. The change in age structure of the population to a greater proportion of males did not affect productivity.

We estimated a mean litter size of 2.92 (measured at the den <7 weeks); however, this did not differ between hunted and unhunted periods. Estimates of litter size have ranged from a low of 1.9 in Florida (Maehr and Caddick 1995) to a high of 3.1 in southeastern British Columbia (Spreadbury et al. 1996), with most averaging around 2.5 (Logan and Sweanor 2001). Logan and Sweanor (2001), Cooley et al. (2009), and most recently Hostetler et al. (2012) have likely produced the least biased estimates of litter size by visiting den sites within the first month of birth, producing means of 3.0 ($n=53$), 2.55 ($n=33$), and 2.6 ($n=94$), respectively. Similarly, our estimated birth interval of 19.8 months closely matched others in the literature, including 17.4 in New Mexico (Logan and Sweanor 2001), 19.7 in Alberta (Ross and Jalkotzy 1992), and 24.3 in Utah (Lindzey et al. 1994).

We found no effect of hunting on maternity rates, and the mean maternity rate of 1.29 was also similar to other published rates (e.g., New Mexico ranged from 1.3 to 1.6 kittens/F/yr [Logan and Sweanor 2001], whereas

Robinson et al. [2008] and Cooley et al. [2009] reported maternity rates in hunted populations of 1.2 and 1.1 kittens/F/yr). Onorato et al. (2011) found the mean age of sires in our population, 35 months (range: 15–57 months), was younger than reported elsewhere. For instance, Logan and Sweanor (2001) found that 71% of litters in their non-hunted population were sired by males 35–88 months of age. However, as indicated above, the younger age structure of the male population during the hunted period did not affect kitten production.

Mean age at dispersal in our study population was similar to other mountain lion studies, where dispersal occurred between 10 and 33 months (Sweanor et al. 2000). Levels of philopatry were also similar to non-hunted populations. Sweanor et al. (2000) found that 68% of female recruits came from the local population, compared to a 50% philopatry rate in juvenile females in our work. We documented 100% male juvenile dispersal following protection from hunting.

Perhaps our most striking finding of the effects of hunting on the characteristics of this mountain lion population was the elimination of emigration during the heavy harvest period. Although this result may suggest a compensatory response (i.e., increased philopatry) of juveniles to reduced conspecific densities, juvenile survival was reduced to a level such that only 2 females and no males survived to dispersal

Figure 4. Projected population levels (\pm 1 SD) for the entire Blackfoot watershed and Garnet study area based on the top population models: 3-segment model (solid black line) and 4-segment model (dashed line). The minimum population for the Garnet study area, based on backdating known-aged animals, is included for comparison (solid gray line).

Figure 5. Sensitivities of mountain lion population growth to matrix vital rates of the 3-segment population model, 2001–2006. Maternity sensitivity is for both the Garnet and Blackfoot hunted area subpopulations in western Montana. For ease of interpretation, we present only sensitivities of the entire watershed population based on the 3-segment model 2001–2006; the sensitivities for all population segments from other population models were similar.

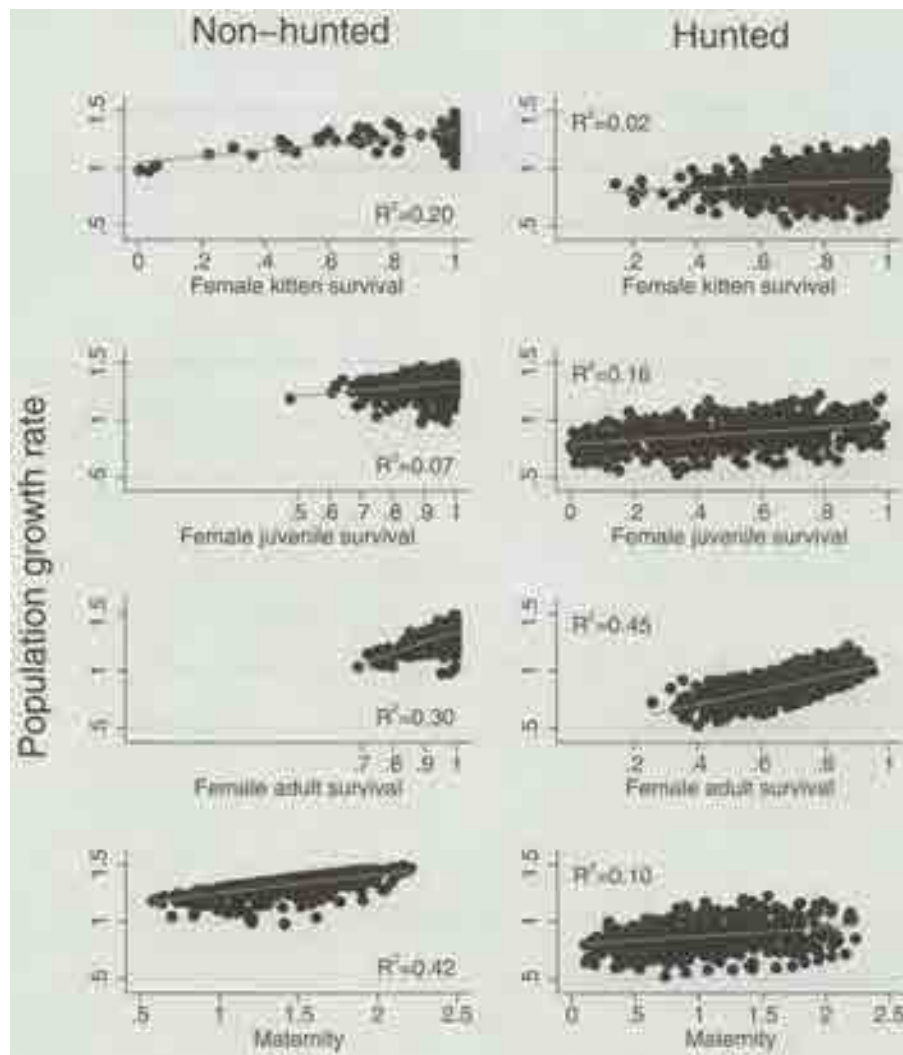

Figure 6. Life-stage simulation analysis (LSA) for mountain lions in the Garnet study area in West-Central Montana during the hunted and protected periods from 1998–2006. The R^2 value describes the proportion of the variation in population growth explained by variation in the vital rate. We omitted values for males because their survival rates and associated variances had little effect on population growth.

age (Table 5). Metapopulation dynamics are an increasingly important focus of mountain lion management and immigration, and emigration can play a major role in balancing hunted and non-hunted mountain lion populations (Beier 1993, Robinson et al. 2008, Cooley et al. 2009). Harvest levels equivalent to those recorded during the first 3 years of our study may severely reduce a population's ability to act as a source of immigration to other areas, affecting not only the focal population level, but also those populations surrounding it (Liu et al. 2011).

Survival and Mortality

Human-caused mortality shaped the survival of mountain lions in our study area, with hunting being the leading cause of mortality. The compensatory mortality hypothesis posits that harvest reduces the probability of animals experiencing other sources of mortality, thus allowing survival rates to remain relatively constant. We found an almost perfectly linear decrease in total survival of adults and juveniles with increased hunting mortality. We also found that mortality

due to all other causes (i.e., illegal, natural, depredation, vehicle, and unknown) was actually lower in the non-hunted population when compared to the hunted population. Both of these findings support the additive mortality hypothesis. The 3-segment model demonstrated the distinct difference between harvest pressures and resultant survival within the Garnet study area and remainder of the Blackfoot following the restriction of hunting in 2001. We interpret the relatively poor performance of the management model as evidence that the small incremental reductions in quotas following 2000 (Table 1) did not result in significant differences in population-level survival rates.

We believe an important mechanism rendering the effects of harvest as additive is kitten mortality due to starvation following harvest of adult females. We found an essentially equal number of kitten mortalities due to the direct effects of hunting through abandonment and natural mortality following closure of the Garnet to hunting. However, because of the timing of hunting mortalities (early in the biological yr), and the longer period of monitoring and

Figure 7. The relationship between mountain lion female kitten survival, adult female survival, and population growth at maternity rates of 1.08, 1.29, and 1.4. Areas above the lines represent possible lambda values greater than 1.0 and areas below represent survival levels that may lead to a decline in population. The dotted reference line represents our kitten survival estimate of 0.785 from 1998 to 2006 in the Blackfoot River watershed, Montana.

sample size following closure of the Garnet to hunting, estimated mortality rates due to hunting were significantly higher. The main influence of hunting on kitten survival may be starvation due to abandonment, not infanticide, and reductions in natural mortality do not compensate for hunting losses of kittens. Our results regarding the additive nature of hunting mortality in mountain lion populations build on Cooley et al. (2009). The additive effects of harvest, not only on adults but also through the orphaning of kittens, suggests that hunting, especially of adult females, shapes survival in hunted populations and has the potential to quickly reduce population levels.

Logan and Sweanor (2001) described the “sledgehammer approach,” where hunting quotas are set mainly by the previous season’s hunter success rate. As success rates decline, quotas may be reduced. However, because of a lack of inexpensive and reliable methods for tracking populations, even reduced quotas may not match existing population levels leading to further declines (Fryxell et al. 2010). Our survival modeling suggested that incremental reductions in quotas outside the protected Garnet study area did not result in significant increases in adult survival until female quotas were reduced to 0, possibly because of a mismatch between quota levels and existing population levels.

Population Modeling and Growth

Matrix population models based on the structure of our 2 top survival models resulted in similar predicted population-level outcomes. They suggested that the mountain lion population in the greater Blackfoot watershed was declining annually between 11% and 12% before protection of the Garnet study area in 2001, but recovered to levels slightly below 1998 by the end of the study in 2007. This was due to protection of the Garnet area, dispersal out of the protected Garnet, and reduced quotas in the remainder of the watershed beginning in 2004. Differences in the predicted level of decline, and the speed and level of the recovery is the result of slightly different estimated survival rates for the various survival

model segments. Our estimates of kitten survival were biased high because of inclusion of kittens first marked as late as 12 months. However, even with this optimistic estimate of kitten survival, both population models predict declining populations in response to the heaviest harvest levels. If our kitten sample was based purely on animals marked at the den, our estimate of survival would most certainly be lower as would our estimate of population growth, thus strengthening our conclusion of harvest being additive.

Our sensitivity analyses showed that maternity was second in importance to female survival rates in influencing population growth rates. Sensitivity analysis does not account for annual variability, as the LSA does. Although maternity rate was held constant for all models at 1.29 kittens per female per year, fecundity is a function of maternity and adult female survival. Differences in fecundity also partially explain the different performance of each model segment.

Sensitivity analysis also showed that dispersal of both juvenile males and females from the protected Garnet into the hunted Blackfoot watershed had a strong negative effect on Garnet population growth and a weak negative effect on growth in the watershed as a whole. The population demonstrated a negative sensitivity of dispersal from the Garnet to the Blackfoot (Fig. 5), which is due to the lower survival rates in the unprotected portion of the Watershed. The matrix model suggested that juveniles would be better off remaining where their probability of survival and reproduction were higher (i.e., inside the Garnet).

Our LSA clearly demonstrated the effect of hunting on the normal population dynamics of mountain lions. In the non-hunted population, adult female survival accounted for approximately 30% of the variation in population growth between years, whereas reproduction (kitten survival and maternity) accounted for approximately 62%. Hunting reversed this balance, shifting the reliance of population growth towards adult survival (45% of the variation in growth), and away from reproduction (12%). In general, we found little effect of male survival on population growth. In the non-hunted segment of our population, male survival accounted for less than 1% of the variability in annual population growth; this level increased to 5% in the hunted population.

By varying 3 important vital rates to population growth (adult female survival, female kitten survival, and maternity) in a deterministic matrix model, we showed that adult female survival rates >0.80 (depending on kitten survival) are required for population growth (Fig. 7). However, kitten survival estimated with minimal bias due to delayed marking (e.g., Cooley et al. 2009, Hostetler et al. 2010) suggests that rates may rarely be >0.50 (see also Logan and Sweanor 2001). At that level, adult female survival <0.85 will likely result in population reduction (Fig. 7). Consistent with these results, Lambert et al. (2006) modeled broad mountain lion population declines in British Columbia, Washington, and Idaho with adult female survival rates of 0.77. Our estimates of mean kitten survival may have been biased high as the average age of a kitten when first marked was 4.7 months. As a result, our population models may slightly overestimate

true growth. However, the predictions of our deterministic model regarding the relationship of kitten survival, adult female survival, maternity, and population growth (Fig. 7) are not affected by our measure of kitten survival.

Immigration and emigration have dramatic effects on real population growth rates when compared to modeled rates that do not account for dispersal. Our population models assumed a closed system consisting of only 2 populations, the Garnet and the remainder of the Blackfoot drainage. We found no juvenile dispersal from the Blackfoot back into the Garnet and therefore could not model the effect of immigration into the Garnet. We found a difference of approximately 8 animals between our modeled population estimates, and our minimum count for the Garnet. This small difference over a 9-year period could be explained by as few as 3 litters that were born inside the Garnet and were not accounted by our estimate of mean maternity rates. However, immigration into the Garnet was likely occurring, but from outside the Blackfoot watershed. Accounting for immigration and emigration, Cooley et al. (2009) showed real population decline ($\lambda = 0.91$) in a heavily hunted area with adult female survival estimated at 0.66. Without immigration, population growth would have been significantly lower, that is, $\lambda = 0.78$. That same study found an essentially stable real population growth rate ($\lambda = 0.98$) in a lightly hunted population with adult female survival of 0.87, with emigration reducing modeled growth from 1.10.

MANAGEMENT IMPLICATIONS

Our research indicates that mountain lion populations are affected by human harvest through additive effects on survival of all age classes and a resultant disruption of juvenile dispersal. We found no effect of harvest on reproductive parameters (i.e., litter size, birth interval, maternity, age at dispersal, and age at first breeding). The consistency in litter size and associated birth interval and maternity rate observed by several studies with varying levels of protection suggests that mountain lions do not possess the ability to respond to harvest through increased reproduction. This lack of elasticity in reproduction and therefore recruitment increases the need for connectivity to facilitate immigration into hunted populations. The high reliance on adult female survival for population growth should dictate very conservative female harvest unless population reduction is the stated management goal. Our results show the strong effect of harvest on targeted populations through shaping survival, and perhaps on neighboring untargeted populations by affecting dispersal patterns. Given the limitations of techniques of abundance estimation currently available and the effect of harvest on mountain lion populations, we recommend lion population objectives and harvest strategies that account for this lack of precision. A source-sink or zone management strategy, as proposed by Logan and Sweeney (2001) would protect the biological integrity of mountain lion populations, while providing public harvest opportunity and flexibility to managers in addressing management concerns.

ACKNOWLEDGMENTS

Project funding and support were provided by the sale of hunting and fishing licenses in Montana and Montana Fish, Wildlife and Parks (FWP) Federal Aid in Wildlife Restoration grants, and the University of Montana. Appreciation is extended to D. Childress, G. Erickson, T. Lonner, J. Herbert, K. Aune, J. Williams, J. Firebaugh, Q. Kujala, and K. McDonald, who secured funding and administered this long-term project. B. Semmens, B. Shinn, G. Hedrick, T. Chilton-Radandt, M. Trapkus, V. Edwards, B. Wiesner, D. Powell, J. Powers, R. Jaffe, T. Knuchel, S. Shrout, S. Powers, A. Jakes, J. Sikich, T. Hollow, M. Graf, C. Kelly, M. Maples, D. Beaver, B. Sheppard, S. McGee, and S. Carson provided invaluable field assistance. Pilots D. Powell, S. Ard, R. Stradley, D. Stradley, R. Gipe, and L. Anderson provided safe and invaluable air support for this project. This work was conducted on BLM, Plum Creek, DNRC and Forest Service lands. We would like to express our appreciation to all private landowners who allowed access to their lands. Any use of trade, firm, or product names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

Special Section on Mountain Sheep Management

The Gordian Knot of Mountain Lion Predation and Bighorn Sheep

ERIC M. ROMINGER,¹ *New Mexico Department of Game and Fish, Santa Fe, NM 87504, USA*

ABSTRACT The objective of this review is to generate a synthesis of research conducted on predation of bighorn sheep (*Ovis canadensis*) and to suggest directions for future research relative to current knowledge gaps and a novel hypothesis. This review is primarily based on literature from the last 60 years on desert bighorn sheep (*O. c. nelsoni*), Rocky Mountain bighorn sheep (*O. c. canadensis*), and mountain lion (*Puma concolor*) predation. Although, many predators kill bighorn sheep, only mountain lions are currently considered to be the primary proximate cause of mortality for many bighorn sheep populations. The ultimate cause of this phenomenon has vexed wildlife managers for >40 years. There are 3 primary reasons for increased predation on bighorn sheep by mountain lions. First, there is an increased presence of mountain lions in habitats where they were historically absent or rare because of the expansion of mule deer (*Odocoileus hemionus*) following the extensive conversion of fire-maintained grasslands to shrublands in the late-1800s. Second, is the extirpation of the 2 dominant apex carnivores (wolves [*Canis lupus*] and grizzly bears [*Ursus arctos*]) during this same time period and a hypothesized numerical response of mountain lions to those extirpations. Finally, the response of mountain lions to the cessation of >70 years of intensive predator control has often resulted in unsustainable mountain lion-bighorn sheep ratios, especially for desert bighorn sheep. Additionally, the effect of mountain lion predation is exacerbated by declines in bighorn sheep that do not result in declines in mountain lions because of their ability to prey switch to mule deer, elk (*Cervus canadensis*), or domestic cattle; kleptoparasitism of mountain lions kills, by ursids and canids, resulting in higher kill rates for mountain lions; and a possible ecological trap where adaptations derived over evolutionary time are no longer adaptive because of human-induced changes in the sympatric apex predator guild. Control of mountain lions, when mountain lion-ungulate ratios are high, might be required to protect small or endangered bighorn sheep populations, and to produce bighorn sheep for restoration efforts. © 2017 The Wildlife Society.

KEY WORDS apparent competition, bighorn sheep, ecological trap, kleptoparasitism, mountain lion, Native American fire, predation, predator control, predator-prey ratio.

Predation on bighorn sheep (*Ovis canadensis*), specifically mountain lion (*Puma concolor*) predation on isolated populations of bighorn sheep, has hindered restoration efforts for bighorn sheep in western North America. This review paper synthesizes our current knowledge and includes a novel hypothesis for the ultimate cause of high mountain lion predation that has confounded wildlife managers for >4 decades. This review is derived primarily from historical literature published in the last 60 years on desert bighorn sheep (*O. c. nelsoni*), Rocky Mountain bighorn sheep (*O. c. canadensis*), and mountain lion predation.

Predation has a profound influence on prey population dynamics in many ecosystems. Laboratory, mesocosm, or natural experiments have assessed the role of predation on non-ungulate prey including relationships between starfish

(*Pisaster* spp.) and tidal pool prey (Paine 1969), mites (*Typhlodromus occidentalis*) and mite prey (*Tarsonemus pallidus* and *Eotetranychus sexmaculatus*; Huffaker 1958), mesocarnivores and waterfowl (Garrettson and Rohwer 2001), weasels (*Mustela nivalis*) and voles (*Microtus agrestis*; Graham and Lambin 2002), mountain lions and porcupines (*Erethizon dorsatum*; Sweitzer et al. 1997), lynx (*Lynx canadensis*) and snowshoe hares (*Lepus americanus*; Krebs et al. 1995), and numerous other species. Hairston et al. (1960:424) noted “herbivores are seldom food-limited and appear most often to be predator-limited.” Excluding anthropogenic associated mortality, only disease has the potential for greater population-level consequences on prey populations (Pedersen et al. 2007).

The scientific literature on predation and ungulates is replete with evidence of the depressive effects that carnivores can have on ungulate populations (Gasaway et al. 1992, Harrington et al. 1999, Hayes et al. 2003, Wittmer et al. 2005, Bergerud et al. 2007). For example, some species of African ungulates increased ≥ 7 times following the removal

Received: 10 October 2016; Accepted: 5 October 2017

¹E-mail: eric.rominger@state.nm.us

of apex carnivores and all prey species <150 kg declined to near pre-removal densities after those predators were reestablished (Sinclair et al. 2003).

Asymptotic densities of ungulate populations, including bighorn sheep, on predator-free islands and in predator-free enclosures are examples of the profound influence the absence of predation can have on prey density. In North America, maximum ungulate densities in those settings are remarkably similar across an array of ecosystems and study area sizes ranging from 2.5–8,000 km² (McCullough 1979, Bowyer et al. 1999, Bergerud et al. 2007, Simard et al. 2010, Rominger 2015). In predator-free environments the median maximum density of deer-size ungulates is approximately 35 individuals/km² and compared to adjacent mainland areas with predators, ungulate densities are generally an order of magnitude, or more, greater (Rominger 2015).

High ungulate densities in the absence of predation have been documented in many cases for decades (Matthews 1973, New Mexico Department of Game and Fish [NMDGF], unpublished data) and for 80–130 years in the case of the Slate Islands, Ontario, Canada, Anticosti Island, Quebec, Canada, and Antelope Island, Utah, USA (Wolfe and Kimball 1989, Potvin et al. 2003, Bergerud et al. 2007) despite dramatic changes in vegetation composition. In other northern hemisphere predator-free islands, the non-irruptive mean ungulate density is like that reported on North American islands (Kaji et al. 2004). Density of tropical fauna is also 10 to 100 times greater on tropical predator-free islands compared with adjacent mainland densities, which mirrors the ratio of ungulate densities on temperate islands to adjacent mainlands (Terborgh et al. 2001).

The predator evasion strategy of bighorn sheep relies on the combination of keen eyesight to detect predators at distance and the ability to navigate steep terrain and outmaneuver predators following visual detection (Geist 1999). Sexual segregation of female and juvenile bighorn sheep, from male bighorn sheep, is hypothesized to be related to anti-predator behavior that includes proximity to steep escape terrain (Bleich et al. 1997). Both strategies are more effective, and therefore likely to have evolved, in response to coursing predators (e.g., wolves [*Canis lupus*]; Festa-Bianchet 1991). These strategies are less effective against a stalking predator (e.g., mountain lions).

Bighorn sheep-predator relationships are associated with potential proximate and ultimate causes. High mountain lion predation on bighorn sheep, particularly desert bighorn sheep and Sierra Nevada bighorn sheep (*O. c. sierrae*) has been the proximate factor hindering restoration in many historical ranges (Wehausen 1996, Hayes et al. 2000, Kamler et al. 2002, Rominger et al. 2004). High mountain lion predation on bighorn sheep, seen since the 1970s, appears to be related to the cessation of intensive predator control used during much of the twentieth century. This release of mountain lions from predator control has resulted in increased mountain lion-bighorn ratios that can be unsustainable based on native ungulate density, especially for desert bighorn sheep (Rominger 2013).

The ultimate cause of high mountain lion predation on bighorn sheep appears to be related to a restructuring of the apex predator guild following the extirpation of wolves and grizzly bears (*Ursus arctos*; Young and Goldman 1944, Brown 1985), major shifts in biotic communities (Berger and Wehausen 1991, McPherson 1995), and the associated restructuring of the ungulate guild across much of western North America. This restructuring has been primarily influenced by the cessation of widespread Native American burning and hunting (Turner 1991, Kay 1995, Stewart 2002), the introduction of livestock and feral equids (Berger and Wehausen 1991, Brown 1994), and the resulting expansion of mule deer (*Odocoileus hemionus*) and mule deer habitats.

Other ecological factors affecting predation and bighorn sheep include apparent competition (Rominger et al. 2004, Johnson et al. 2013), specialist predators (Ross et al. 1997, Logan and Sweaner 2001, Knopff and Boyce 2007, Knopff et al. 2010), kleptoparasitism (Elbroch et al. 2015), vulnerability of small populations (Berger 1990), subsidized predators (Rominger et al. 2004), indirect effects of predation (Bourbeau-Lemieux et al. 2011), and declining native prey (Unsworth et al. 1999). The extirpation of wolves and grizzly bears from the predator guild associated with bighorn sheep resulted in mountain lions becoming the primary bighorn sheep predator. This human-induced change might have resulted in an ecological trap (Dwernychuk and Boag 1972, Schlaepfer et al. 2002). Continued restoration of wolf and grizzly bear populations throughout Rocky Mountain and desert bighorn sheep habitat will add complexity associated with multi-predator, multi-prey systems (Knopff and Boyce 2007, Kortello et al. 2007, Knopff et al. 2010, Ruth et al. 2011) compared to many systems that only have had mountain lions as a resident apex carnivore for most of the last century.

Virtually all predators, sympatric with bighorn sheep, ranging in size from gray fox (*Urocyon cinereoargenteus*) to grizzly bear, have been documented to prey upon bighorn sheep (Sawyer and Lindzey 2002) and except for foxes, have been documented to prey on adults and juveniles. Although smaller predators (e.g., coyotes [*Canis latrans*], bobcats [*Lynx rufus*], and golden eagles [*Aquila chrysaetos*]), and less cursorial predators (e.g., black bear [*U. americanus*] and grizzly bear) are likely more effective predators of neonates, mountain lions have been documented as the primary predator of lambs (Parsons 2007, Smith et al. 2014, Karsch et al. 2016).

The consensus in the earliest review of the effects of predation on desert bighorn sheep was that no predators had population-level consequences (Desert Bighorn Council [DBC] 1957). At the inaugural DBC meeting, a special session on predation concluded that bobcats and golden eagles were the primary predators of desert bighorn sheep but that neither species limited population demographics (DBC 1957). Most biologists working on desert bighorn sheep thought that mountain lion numbers were so low, and the predator-control programs so strict (private and government year-round trapping and hunting, bounties, poisons), that

mountain lions simply could not induce population declines. The first monograph and 2 of the earliest books on Rocky Mountain and desert bighorn sheep ecology (Buechner 1960, Geist 1971, Monson and Sumner 1980) were written during a period when mountain lions were unprotected, or just recently protected by law, and wolves had been extirpated from all bighorn sheep habitats in the conterminous United States (Young and Goldman 1944). Mountain lion predation was not considered to be an important influence on bighorn sheep population dynamics.

In contrast, 5–6 decades later, a different predator-management paradigm, with mountain lions protected throughout the United States (except TX) and Canadian provinces, has shifted our interpretation of the consequences of predation. The demographic recovery of mountain lions in virtually all bighorn sheep ranges, and the advent and use of radio-telemetry to assess mortality causes, has resulted in multiple examples of population-level effects of mountain lion predation on bighorn sheep (Harrison and Hebert 1988, Wehausen 1996, Hayes et al. 2000, Rominger et al. 2004, Festa-Bianchet et al. 2006). In a recent review, Sawyer and Lindzey (2002) determined that mountain lions were capable of depressing bighorn sheep populations and numerous publications have corroborated that conclusion (Kamler et al. 2002, McKinney et al. 2006, Foster and Whittaker 2010, Brewer et al. 2013, Johnson et al. 2013).

CHANGES IN THE PREDATOR-PREY COMMUNITY

Predation on bighorn sheep hypothetically has been influenced by a change in the apex predator guild following the extirpation of wolves and grizzly bears and a change in the ungulate guild following the conversion of much of western North America from a grassland ecosystem maintained with fire by Native Americans to a shrub-dominated ecosystem. Changes in the ungulate guild are primarily related to the extensive range expansion of mule deer throughout large portions of bighorn sheep range (Berger and Wehausen 1991, Turner 1991, McPherson 1995, Kay 1995, Stewart 2002).

Changes in Predator Guild

Grizzly bear and wolf distribution overlapped nearly all Rocky Mountain bighorn sheep range and some desert bighorn ranges (Young and Goldman 1944, Lamb et al. 2017). These 2 predators were absent only from the most xeric parts of Mexico, western Arizona, California, and Nevada (Young and Goldman 1944, Lamb et al. 2017). The extirpation of wolves (Young and Goldman 1944) and near extirpation of grizzly bears (Brown 1985, Lamb et al. 2017) is well documented. Mountain lions are subordinate to wolves and bears (Boyd and Neale 1992, Kortello et al. 2007, Ruth et al. 2011, Elbroch et al. 2015) and much like the well documented response of subordinate coyotes to the absence of wolves (Berger and Gese 2007, Merkle et al. 2009), mountain lions almost certainly have responded numerically to competitive release from these 2 dominate carnivores. Evidence of this subordination is the observation

that when pursued by hounds, mountain lions in North America will climb trees. In South America, where mountain lions did not evolve with a large canid predator, they do not climb trees when pursued by hounds (B. M. Jansen, Arizona Game and Fish Department [AZGFD], personal communication.). Although the total cost to mountain lions of sympatry with wolves has not been assessed, it is hypothesized that interactions could affect reproduction, survival rates, habitat selection, and home range size (Kortello et al. 2007, Ruth et al. 2011). Mountain lion survival was negatively affected by increasing annual wolf use, wolves were responsible for 15% of adult mountain lion deaths, and wolf predation decreased annual kitten production 10–39% (Ruth et al. 2011).

Anecdotal evidence suggests that mountain lions and coyotes were rare or absent where grizzly bears and wolves occurred in New Mexico (Barker 1953, Stevens 2002). Stevens (2002) hunted grizzly bears, black bears, and mountain lions with dogs throughout the late 1800s, in the portion of New Mexico that is now the Gila Wilderness, but only mentioned 2 mountain lions in his book. In 1882, a Professor Dyche from the University of Kansas came to New Mexico to collect grizzly bears in what is now the Pecos Wilderness. Using a tree blind and a deer for bait, Dyche reported bobcats and foxes but not a single coyote in his diary, although they became common after the turn of the century following the extirpation of wolves (Barker 1953).

Extirpation of wolves and grizzly bears was facilitated by intensive predator control. Private predator control efforts began in the western United States soon after livestock was introduced following the end of warfare with Native Americans. In 1914, following a Congressional appropriation, federal agencies employed 300 predator control agents to protect livestock and remnant wild ungulate populations (Brown 1992). Control efforts included year-round trapping, poisoning, hunting with hounds, denning, and bounties paid from private and government sources (Buechner 1960, Brown 1992).

Xeric ecoregions with sufficient numbers of deer to maintain resident mountain lions, but without wolves or grizzly bears, presumably functioned much like systems where high mountain lion predation on bighorn occurs today. Historical accounts suggest that native ungulate densities may have been low in multi-prey ecosystems with sympatric mountain lions as the primary apex predator. As Charles Sheldon embarked on a bighorn sheep hunt into Mexico in 1915, his guide remarked that he had recently been to the Sierra Pintas in Arizona and “lions are numerous there but sheep are scarce” (Sheldon 1979:66). During the 1907 William Hornaday expedition from Tucson, Arizona to the Pinacate Mountains in Sonora, Mexico, a single adult deer was seen in a trip that lasted more than 30 days (Hornaday 1908).

Mountain lions may have been less common historically because of interspecific competitors (Stevens 2002, Riley et al. 2004, Wittmer et al. 2005) and a much more limited distribution of mule deer (Berger and Wehausen 1991, Potter 1995, Heffelfinger and Messmer 2003). Although

mountain lion abundance might have been briefly released following the extirpation of wolves, >70 years of intensive predator control kept numbers low. Quantifying abundance of mountain lions is difficult (Logan and Sweaner 2001) and there are no reliable estimates from periods of intensive predator control. Bounty records from 1902–1906 in Montana indicate that bounties paid for wolves outnumbered those paid for mountain lions by >30:1. By region, there was an inverse relationship between the number of wolves and mountain lions for which a bounty was paid suggesting that in areas where wolves were prevalent, mountain lions were rare (Riley et al. 2004).

Changes in Prey Guild

Grasslands were maintained across western North America with fire by Native Americans for millennia (Turner 1991, Kay 1995, McPherson 1995, Stewart 2002). Shrubs, which are the primary forage of mule deer, were an inconspicuous component of desert grasslands prior to 1880 (McPherson 1995). Reports of mule deer were rare in the diaries of early travelers and were reported to be a minor component of Native American diets (Berger and Wehausen 1991, Potter 1995, Heffelfinger and Messmer 2003, Kay 2007). The landscape conversion, of historical grasslands to shrub or chaparral, was influenced by grazing of excessive numbers of livestock and feral equids (Berger and Wehausen 1991). This conversion resulted in range expansion of mule deer and concomitantly the presence of mountain lions (Berger and Wehausen 1991). This conversion of grasslands to chaparral and shrublands occurred throughout bighorn sheep ranges in western North America. Range expansion of mountain lions following invasion by white-tailed deer (*Odocoileus virginianus*) into areas of clear-cut old-growth forests converted to shrub-dominated habitats also has been documented (Compton et al. 1995, Wittmer et al. 2005).

The 500,000-km² Great Basin ecoregion is hypothesized to have been void of deer and mountain lions because grass-dominated basin and range habitats, maintained by burning by Native Americans, did not support deer (Berger and Wehausen 1991). The Great Basin contains extensive bighorn sheep habitat and pronghorn (*Antilocapra americana*) and bighorn sheep were likely the primary ungulates present in this vast landscape. Therefore, bighorn sheep in the Great Basin may have encountered little predation by mountain lions just 125 years ago. Niche separation between pronghorn and bighorn sheep would have resulted in this ecosystem functioning much like a single-prey system. Analysis of Native American diets at 2 pueblo sites in New Mexico reported the ratio of pronghorn specimens to deer specimens was 25:1 and 79:1, respectively (Potter 1995).

Mountain lions are most effective at limiting bighorn sheep populations when they are able to prey switch onto deer, elk, or cattle and there is little evidence that mountain lions can limit bighorn sheep populations without alternative prey (Berger and Wehausen 1991, Wehausen 1996). Resident mountain lions were undocumented in bighorn sheep habitat of the Providence and New York Mountains, California, United States, until the introduction of mule deer (R. A. Weaver,

California Department of Fish and Wildlife, personal communication). Mountain lion predation is rare in the most xeric mountain ranges without sympatric deer or livestock (Berger and Wehausen 1991, Cronin and Bleich 1995).

THE PARADOX OF MOUNTAIN LION DENSITY

Regardless of the mechanisms that have resulted in the predator-prey guilds present today, it is the current ratio of mountain lions to native ungulate populations that appears to influence the primary proximate cause of mortality for bighorn sheep. Following decades of intensive predator control, mountain lions have increased numerically and in distribution (Fecske et al. 2011, Knopff et al. 2014). Predator control across North America was initially directed primarily toward wolves; however, the emphasis switched to mountain lions, black bears, and coyotes following the near-extirpation of wolves. Some states paid higher bounties for female mountain lions to incentivize population reduction (Buechner 1960). Until the cessation of large-scale predator control, mountain lion predation on bighorn sheep populations was insignificant (DBC 1957).

In a review of 12 studies assessing the effects of sport hunting on mountain lions, the range of densities was 1.1–7.1 mountain lions/100 km², although the low density does not include subadults or kittens (Cooley et al. 2011). A density of 1–3 mountain lions/100 km² when coupled with a standard ungulate kill rate (Wilckins et al. 2016) may have a profound influence on ungulate population dynamics (Table 1).

Global positioning system (GPS) collaring of mountain lions has allowed for a refinement of kill rates by visiting waypoint clusters associated with kills and most studies have confirmed that mountain lions kill about 1 ungulate/week (Anderson and Lindzey 2003, Knopff et al. 2009, Wilckins et al. 2016). This value is used as the mean for calculating the number of ungulate kills/100 km² with the 95% confidence interval for a high and low kill rate (Table 1; Wilckins et al. 2016). At a high density of 3 mountain lions/100 km² and a high kill rate of 1.1 ungulate/week, there would be a predicted 172 kills/100 km² annually (Table 1). Most small desert bighorn sheep populations in New Mexico were predicted to go extinct with 5% additive mountain lion mortality (Fisher et al. 1999). For 172 kills to be 5% of a wild ungulate population, the density required would be 3,440 ungulates/100 km². At a low density of 1 mountain lion/100 km² and a low kill rate of 0.9 ungulate/week there would be 47 kills annually (Table 1). For 47 kills to be 5% of a wild ungulate population, the density required would be 940 ungulates/100 km². Both numbers are essentially 1–2 orders of magnitude greater than currently estimated ungulate densities in desert bighorn sheep ranges in New Mexico (Bender et al. 2012, Rominger 2013). This is the paradox that influences high mountain lion predation in desert bighorn sheep ranges. Cunningham et al. (1999) estimated that 44% of mountain lion dietary biomass was comprised of livestock at an Arizona study area. The fact that mountain lions are a subsidized predator (Soule et al. 1988) is a partial explanation for their ability to persist despite low native

Table 1. Kills as a percentage of 3 hypothetical deer-size ungulate-prey population densities using 3 values of mountain lion density and 3 values of kill rates (e.g., low lion density [1.0] \times low kill rate [0.9] \times 52 weeks = 47 kills/annually). The final column is number of deer-size ungulates/100 km² required for the number of kills to be a 5% mortality rate (e.g., 47 kills/5 \times 100) = 940.

Mountain lion density/100 km ^{2a}	Mountain lion weekly kill rates ^b (no. prey)	No. annual kills	Annual % mortality ^c at 50 prey/100 km ²	Annual % mortality ^c at 100 prey/100 km ²	Annual % mortality at 200 prey/100 km ²	No./100 km ² if % mortality = 5%
1	0.9	47	94	47	24	940
1	1.0	52	>100	52	25	1,040

ungulate densities (Cunningham et al. 1999, Rominger et al. 2004).

In the Fra Cristobal Mountains, New Mexico, mountain lion control conducted from 1999 until 2013 resulted in the highest estimated ungulate density of any desert mountain range in the state (New Mexico Department of Game and Fish [NMDGF], unpublished data). The combined bighorn sheep and mule deer density is approximately 400/100 km² (NMDGF, unpublished data). From 2003 to 2013, an average of 3.3 mountain lions were killed annually on the 107-km² mountain range (NMDGF, unpublished data). However, even at this high ungulate density, 2 resident mountain lions could potentially kill nearly 25% of the resident ungulates annually.

A long-term mountain lion study on the San Andres Mountains, New Mexico documented 1.72–4.25 mountain lions/100 km² including adults, subadults, and cubs. This study was completed in 1995 just as high mountain lion predation adversely affected mule deer density and was also the predominant mortality cause associated with the biological extinction of desert bighorn sheep (Logan and

Sweaner 2001, Rominger and Weisenberger 2000). Following this study, mule deer density declined to one of the lowest ungulate densities reported in North America with an estimated 10–12 deer/100 km² (Bender et al. 2012, Rominger 2013). Although mountain lion density in the San Andres Mountains is currently unknown, they persist in this habitat despite a very low deer density. There has been no discernable recovery of mule deer in >20 years.

DIRECT PREDATION

Although predation by mountain lions had been anecdotally noted by several authors (Leopold 1933, DBC 1957, Blaisdell 1961), it was not until the earliest stages of the restoration of desert bighorn sheep in Texas that high mountain lion predation was documented to cause population declines (Kilpatrick 1976). In rapid succession, other western states and provinces began documenting instances of high mountain lion predation (Table 2). Most early data are reported as a percentage of radio-collared bighorn sheep killed annually (Muñoz 1982, Harrison and Hebert 1988, Creeden and Graham 1997, Ross et al. 1997).

Table 2. Examples of high mountain lion predation on bighorn sheep (bhs) in western North America.

Location	Year	Citation	Specifics
TX	1975	Kilpatrick (1976, 1982)	21 bhs killed inside captive breeding facility by mountain lions at Black Gap State Wildlife Area; the wild population estimated to have declined from 20 to <10
NM	1979	Muñoz (1982)	9 of 25 (36%) bhs killed by mountain lions in 14 months
NM	1980–1989	Hoban (1990)	22 of 43 bhs mortalities attributed to mountain lion predation
NM	1996–1997	Rominger and Weisenberger (2000)	Bhs decline from ~25 to 1 resulting in biological extinction. Mountain lion predation the primary cause of death
BC	1986–1988	Harrison and Hebert (1988)	2 female mountain lions kill a minimum of 21 bhs in 14 months
CO	1995	Creeden and Graham (1997)	5 of 14 (36%) radio-collared bhs killed by mountain lions within 12 months
AB	1985–1994	Ross et al. (1997)	13% of winter bhs population killed; 1 female mountain lion killed 9% of total population and 26% of lambs in 1 winter
OR	1995–2002	Foster and Whittaker (2010)	Hart Mountain bhs herd declined from 600 to 125 with mountain lion predation the primary cause of mortality
CA	1997–1999	Schaefer et al. (2000)	Mountain lion predation cause of 75% of bhs mortality
CA	1976–1988	Wehausen (1996)	49 bhs documented killed by mountain lions without telemetry
AZ	1979–1997	Kamler et al. (2002)	In meta-analysis of 365 translocated bhs, 66% of mortality was mountain predation

Table 3. Cause-specific mortality rates (CSMR) on bighorn sheep (bhs) attributed to mountain lion predation in western North America.

Location	Year	Citation	Mortality rates
CA	1988–1995	Wehausen (1996)	CSMR due to mountain lions was 0.38
AZ	1979–1997	Kamler et al. (2002)	In meta-analysis of 365 translocated bhs, the highest CSMR due to mountain lions was 0.29
AZ	1993–1996	Bristow and Olding (1998)	CSMR due to mountain lions was 0.12 for females and 0.15 for males
NM	1992–2000	Rominger et al. (2004)	CSMR due to mountain lions was 0.13 for males and 0.09 for females in desert habitat
OR	2004	Foster and Whittaker (2010)	CSMR due to mountain lions for 44 radio-collared bhs was 0.17 for males and 0.10 for females
AB/MT	1983–2003	Festa-Bianchet et al. (2006)	During years of high mountain lion predation, the CSMR due to mountain lions was 0.26 for males and 0.32 for females
CA	1992–1998	Hayes et al. (2000)	CSMR due to mountain lions for 113 radio-collared bhs ranged between 0.08 and 0.26

The development of survival models (Heisey and Fuller 1985, White and Burnham 1999) that incorporate data from telemetrically monitored bighorn sheep, allow researchers to calculate cause-specific mortality rates (CSMR; Table 3). Mountain lion-specific mortality rates of adult bighorn sheep have been as high as 0.26 (Hayes et al. 2000), 0.29 (Kamler et al. 2002), and 0.31 (Goldstein and Rominger 2012) in some ranges. Statewide lion-specific mortality rates for desert bighorn sheep in New Mexico between 1992 and 2002 were 0.16 (Goldstein and Rominger 2012) and 88% of New Mexico desert bighorn sheep populations went extinct or declined to <10 females during this period.

The high mortality rates on state-endangered desert bighorn, attributed to mountain lion predation, in New Mexico during the 1990s were unsustainable and caused populations to decline rapidly (Goldstein and Rominger 2012). However, substantially lower mountain lion mortality rates are projected to be detrimental to the persistence of small populations of bighorn sheep. A Vortex model for state-endangered desert bighorn sheep in New Mexico predicted that all extant populations had a 100% probability of extinction with just 10% mountain lion predation added to baseline non-predation demographic parameters (Fisher et al. 1999). Initial population sizes of these small herds ranged from 10–120 and just a 5% mountain lion predation rate induced an extinction probability of 0.82–1.0 for 6 extant herds (Fisher et al. 1999).

Following the initiation of mountain lion control in desert bighorn sheep ranges in New Mexico, numbers increased from <170 in 2001 to >1,100 in 2016 (Fig. 1; Ruhl and Rominger 2015). After 31 years on the New Mexico threatened and endangered species list, desert bighorn sheep were delisted in 2012 and returned to a state-protected game species (Rominger et al. 2009, Goldstein and Rominger 2013).

Predation is the dominant cause of mortality for ungulate neonates (Smith et al. 1986, Scotton 1998, Gustine et al. 2006, Quintana et al. 2016). Predation caused 82% and 86% of mortality of desert bighorn sheep lambs in 2 studies in New Mexico (Parsons 2007, Karsch et al. 2016). In both studies, mountain lions were the apex predator.

Although wolves are currently considered to be a predator of minor consequence, as mountain lions were in 1957, wolves are still recolonizing many Rocky Mountain bighorn sheep ranges and have just begun to re-occupy historical

desert bighorn sheep ranges in Arizona and New Mexico. The ecological relationship between wolves and mountain lions is not well understood (Hussemann et al. 2003, Kortello et al. 2007, Ruth et al. 2011, Krawchuck 2014) and research has been primarily conducted in ecosystems recently recolonized by one or both predators, or where both carnivores have responded to less intensive predator control (Knopff and Boyce 2007, Kortello et al. 2007, Ruth et al. 2011). Most of these studies have reported mountain lions to be subordinate to wolves resulting in usurpation of kills, direct mortality of adult and juveniles, and constriction of home ranges (Boyd and Neale 1992, Kortello et al. 2007, Ruth et al. 2011).

In North American ecosystems occupied by Dall's sheep (*O. dalli dalli*), the primary predator is the wolf and there is little evidence of consistent population-level consequences of predation (Barichello and Carey 1988, Hayes et al. 2003), although Bergerud and Elliot (1998) reported improved recruitment of Stone's sheep (*O. d. stonei*) following the reduction of wolf numbers in British Columbia. Barichello and Carey (1988) reported no evidence that a substantial reduction in wolf density influenced demographics of Dall's sheep. However, Arthur and Prugh (2010) reported high

Figure 1. Desert bighorn sheep population estimates, New Mexico, 1980–2016. From 1979–1999, there were 253 desert bighorn sheep released into wild populations. From 2000–2016, there were 274 desert bighorn sheep released into wild populations. Mountain lion control began in 1999 in all endangered desert bighorn sheep herds when statewide population estimates declined to <170 in 6 herds.

levels of Dall's sheep lamb mortality by coyotes, which are hypothesized to have increased because of wolf control.

Coyotes are reported to kill adult and juvenile ungulates (Hass 1989, Kelley 1980) and were the second-most important predator of juvenile desert bighorn sheep after mountain lions in the Peloncillo Mountains, New Mexico (Karsch et al. 2016). Coyotes may be more effective predators than wolves on wild sheep neonates (Arthur and Prugh 2010) and the extirpation of wolves has resulted in a competitive release of coyotes (Berger and Gese 2007). Hebert and Harrison (1988) reported coyote predation as a major source of lamb mortality in British Columbia, Canada, and that predator control targeting coyotes was responsible for a 2–2.5-fold increase in lamb:female ratios. Bobcats are reported to kill adult and juvenile ungulates (Kelley 1980, DeForge 2002); however, there is little evidence that they have population-level effects on bighorn sheep populations. Bobcats were not confirmed to have killed desert bighorn sheep lambs in the 2 New Mexico studies (Parsons 2007, Karsch et al. 2016).

Most bighorn sheep herds are comprised of <100 individuals (Berger 1990) and therefore may be more vulnerable to extinction (Berger 1990, Fisher et al. 1999), although Wehausen (1999) found less support for a strong population size effect on extinction probability. High levels of predation can cause the extirpation of small isolated populations of bighorn sheep (Rominger and Weisenberger 2000), woodland caribou (*Rangifer tarandus*; Kinley and Apps 2001), and other species (Williams et al. 2004). However, bighorn sheep populations >100 also have been documented to decline substantially, with mountain lion predation the primary cause of mortality (Wehausen 1996, Hayes et al. 2000, Foster and Whittaker 2010).

Bighorn sheep populations with sympatric deer have been documented to decline to low density, with mountain lion predation the primary mortality factor (Wehausen 1996, Foster and Whittaker 2010, Rominger 2013). This apparent competition in multiple-prey systems was first described by Holt (1977) and has been documented in bighorn sheep populations (Rominger et al. 2004, Johnson et al. 2013) and other ungulates (Bergerud and Elliot 1986, Harrington et al. 1999, McLellan et al. 2010, Wittmer et al. 2014). For Sierra Nevada bighorn sheep, the more common prey species is mule deer (Johnson et al. 2013); however, in most desert bighorn sheep habitats in Arizona and New Mexico, domestic cattle, usually juveniles, are also alternative prey (Cunningham et al. 1999, Rominger et al. 2004).

The usurpation of mountain lion kills by interspecific competitors, primarily bears or wolves, can influence predation dynamics. In Colorado and California, mountain lion kill rates increased 48% in the presence of sympatric black bears because of kleptoparasitism, with bears detected at 48–77% of mountain lion kills (Elbroch et al. 2015). Although mountain lions may occasionally kill small black bears at cache sites, it appears that mountain lions generally depart permanently following the arrival of larger black bears (Elbroch et al. 2015). Wolves were documented to usurp 12% and scavenge 28% of mountain lion kills during a 4-year

period (Kortello et al. 2007). In southern British Columbia, where wolves and grizzly bears were extirpated, or greatly reduced, mountain lions are the dominant predator of woodland caribou (Compton et al. 1995, Kinley and Apps 2001, Wittmer et al. 2005). However, in north-central British Columbia, where wolves and grizzly bears persist, mountain lions are not the dominant predator (Wittmer et al. 2005).

After work by Ross et al. (1997) that documented high mortality on a wintering bighorn sheep herd by an individual mountain lion, it has been debated whether most predation on bighorn sheep is a function of specialist mountain lions. Although, specialist predators exist (Ross et al. 1997, Logan and Sweanor 2001, Knopff and Boyce 2007), other data suggest that most sympatric mountain lions will kill bighorn sheep. In the Peninsular Ranges of California, 18 of 23 individually identified mountain lions were associated with bighorn sheep kills (Ernest et al. 2002) and in the Fra Cristobal Mountains, New Mexico 16 of 18 radio-collared mountain lions either killed or attempted to kill desert bighorn sheep (NMDGF, unpublished data).

The predator-evasion strategy of bighorn sheep is far more effective against a coursing predator than a stalking predator (Festa-Bianchet 1991) and the abrupt removal of wolves and widespread replacement by mountain lions may have resulted in an evolutionary trap where past selection pressures shaped cue-response systems that were adaptive but no longer are in the face of human-induced changes. Additionally, the sexual segregation behavior of bighorn sheep might be associated with the potential for an ecological trap. Mortality rates for female bighorn sheep, attributed to mountain lion predation can be as high or higher than those for males, suggesting the benefit of this sexual segregation strategy is not particularly effective against mountain lion predation (Krausman et al. 1989, Hayes et al. 2000, Kamler et al. 2002, Festa-Bianchet et al. 2006).

DISCUSSION

Recent studies throughout western North America provide evidence that direct predation by mountain lions is a primary proximate mortality factor of bighorn sheep. The increase in mountain lion predation on bighorn sheep has followed the demographic recovery of mountain lion populations following the cessation of intensive predator control efforts. The recovery of mountain lions was preceded by expansion of their primary prey, mule deer, following the vast conversion of grasslands that had been maintained with fire by Native Americans. This shift in the mountain lion prey guild allowed for range expansion of mountain lions into habitats where wolves and grizzly bears have been extirpated. The combination of restructured predator-prey guilds and elimination of Native American fire and hunting has resulted in bighorn sheep with sympatric mountain lion densities unlikely to have occurred previously.

Additionally, livestock and feral equids responsible for conversion of grasslands contribute to the alternative prey-base for mountain lions. In ecosystems with low densities of native prey, cattle subsidize mountain lion populations and

may comprise >40% of the biomass in mountain lion diets, precluding a decline in mountain lion numbers despite declining native ungulate populations (Cunningham et al. 1999, Rominger et al. 2004). Feral equids are also reported to subsidize mountain lion populations, although they are much less numerous than cattle (Berger 1986, Turner et al. 1992, Knopff and Boyce 2007). Low densities of native ungulates are correlated with increased depredation of livestock by felids and canids (Brown 1992, Khorozyan et al. 2015).

The intensity of mountain lion predation has been reported to be nearly continuous in some ecosystems and more pulse-like in other ecosystems (Ross et al. 1997, Rominger et al. 2004). Because bighorn sheep density is rarely but a fraction of that observed on predator-free islands and predator-free enclosures, most predation is considered additive mortality, especially at low bighorn sheep densities. The stalking hunting style of mountain lions is hypothesized to result in more prime-age bighorn sheep kills compared to the effect of a coursing hunting style (e.g., wolves), which exposes compromised individuals. Additionally, the encroachment of woody vegetation due to the exclusion of fire for more than a century has enhanced stalking cover for mountain lions (Wakelyn 1987).

Increased mountain lion predation and related declines in New Mexico desert bighorn sheep populations have been correlated with declines in sympatric mule deer. These populations declined sharply in the mid-1990s and there has been no discernable recovery in the last 20 years (Rominger and Weisenberger 2000, Bender et al. 2012, NMDGF, unpublished data). Observations of deer during helicopter surveys in the San Andres Mountains were as high as 150 deer/hour and have declined to <5.5 deer/hour for all bighorn sheep surveys flown since 1996 (NMDGF, unpublished data). The estimated deer density in the San Andres has declined to 0.08–0.11 mule deer/km², making this one of the lowest densities of North American ungulates ever reported (Bender et al. 2012, Rominger 2013). Because of this low density, there has been no deer hunting on the entire 8,300-km² White Sands Missile Range, New Mexico since 1999. Similarly, low mule deer observation rates have been recorded in all other desert bighorn sheep surveys in New Mexico for the last 20 years (NMDGF, unpublished data). However, it was the ratio of mountain lions to these very low-density ungulates that precluded recovery and has required mountain lion control to increase desert bighorn sheep numbers.

Declines in bighorn sheep populations, due to mountain lion predation, have been reported for nearly every state and province where this species occurs. There is little evidence that these populations recover in the absence of predator control. One exception appears to be the federally endangered Peninsular bighorn sheep population. Although this herd is still listed as endangered, it has increased from approximately 275 (Rubin et al. 1998) to approximately 980 (Botta 2011) without mountain lion control. Peninsular bighorn sheep have an elevational niche separation from mule deer that use habitat at higher elevations in the Peninsular Ranges (Hayes et al. 2000), much like the niche

separation of pronghorn and bighorn sheep in the Great Basin (Berger and Wehausen 1991). Thus, mountain lions hunting in low-elevation desert bighorn habitat have virtually no opportunity to prey switch onto deer without vacating bighorn sheep habitat.

Management of predation deemed excessive relative to bighorn sheep population objectives generally involves lethal predator control. Controlling apex carnivores is much more controversial than culling mesocarnivores (Reiter et al. 1999, Rominger 2007) despite documented success in the protection and recovery of endangered species (Hecht and Nickerson 1999, Rominger et al. 2009, Johnson et al. 2013, Hervieux et al. 2014).

Predator control is used by most western state and provincial wildlife agencies to protect endangered ungulate species (Hervieux et al. 2014) and big game populations (Rominger 2007). Predator control to protect translocated desert bighorn was first advocated by Wilson et al. (1973) and has been used to aid the restoration of bighorn sheep in New Mexico, California, Texas, Arizona, Utah, and elsewhere (Rominger 2007). High levels of mountain lion predation associated with desert bighorn sheep translocations and some Rocky Mountain bighorn sheep translocations (Krausman et al. 1999, Rominger et al. 2004, McKinney et al. 2006) can be reduced by removing resident mountain lions prior to translocation. After multiple failed translocations due to mountain lion predation, NMDGF no longer translocates desert bighorn sheep without a pre-treatment mountain lion control program to reduce the density of resident mountain lions, usually beginning 3–4 months prior to translocation.

Following the extirpation of desert bighorn sheep in the Catalina Mountains, Arizona in the 1980s, desert bighorn sheep were released into historical habitat in 2013 (Krausman 2017). The initial translocation, done without a pre-treatment removal of resident mountain lions, had high mortality with mountain lions killing 15 of 30 radio-marked bighorn sheep within 4 months. Post-release control of offending mountain lions resulted in the lethal removal of 7 mountain lions. To date, mountain lions have killed a minimum of 27 of 86 radio-marked bighorn sheep from 3 releases. In the absence of mountain lion control, this attempted restoration of a native faunal component would have almost certainly failed.

Ernest et al. (2002) modeled predator control management options to mitigate mountain lion predation and determined that for populations or subpopulations with <15 females, range-wide control (habitat control) of mountain lions was the most effective paradigm. At higher female numbers, less strict take of mountain lions was recommended (e.g., only remove offending mountain lions [kill-site removal]). However, this model assumes that a documented offending mountain lion will be removed prior to making additional kills. A large data set from NMDGF suggests this is unlikely and offending mountain lions were taken at <20% of bighorn sheep kills (Rominger et al. 2011). During a period of range-wide mountain lion control, 68 mountain lion-killed bighorn sheep with very high frequency (VHF)

radio-collars were documented. However, only 13 (19%) offending mountain lions were culled.

The 2 primary reasons mountain lions were not culled were the bighorn sheep kill was not detected and located prior to the mountain lion departing (59% of all kills) and the mountain lion was present but missed at the kill site (54% of attempted removals were unsuccessful because the mountain lion did not step into snare, substrate was not conducive to snare placement, hounds were unable to tree or bay mountain lion). Although sample sizes were substantially reduced, the data set was partitioned between attempts to snare offending mountain lions and attempts to hound-hunt offending mountain lions. Use of hounds was successful in 5 of 14 attempts, whereas use of snares was successful in 8 of 14 attempts (Rominger et al. 2011). Culling offending mountain lions in the Catalina Mountains, Arizona restoration project has been successful in 6 of 15 attempts and this higher success rate is attributed to the use of GPS collars that alerted managers to mountain lion kills more quickly than VHF radio-collars (B. D. Brochu, AZGFD, personal communication).

Trapping and translocation is the primary management tool used to reestablish bighorn sheep populations into unoccupied habitats (Foster 2004). Currently, most bighorn sheep used for translocation come from mountain lion-free islands (e.g., Tiburon Island, Sonora, Carmen Island, Baja California Sur, MX; Wild Horse Island, MT, USA, Antelope Island) or predator-free enclosures (e.g., Red Rock, NM, USA and Pilares, Coahuila, MX). Very few desert bighorn sheep populations with uncontrolled sympatric mountain lions produce surplus bighorn sheep for translocations.

Restoration of natural grasslands, maintained by frequent fires, at scales that would substantially reduce deer numbers is unlikely to be a near-term management option. However, most state and provincial agencies have developed habitat management plans to reduce woody vegetation to increase bighorn habitat, and potentially reduce stalking habitat for mountain lions. Although, mountain lion predation seems to be lowest in single-prey systems in the most xeric habitats, most bighorn sheep currently occur in habitats with multiple sympatric ungulates. It is hypothesized that high levels of alternative buffer prey are preferable to low-density buffer prey when habitats have high mountain lion density.

Kill rates may increase substantially in ecosystems with high levels of kleptoparasitism and if deemed excessive, population reduction of kleptoparasites, specifically bears, would be a novel management action. The cumulative effects of predation on all sex and age classes of a bighorn sheep population must be recognized. Total predation in ecosystems with a diverse predator guild may have a much more profound influence on bighorn sheep demography; therefore, wildlife managers must decide on the appropriate response relative to management needs (Griffin et al. 2011). Small, isolated bighorn sheep herds, reduced to very low numbers by predation, will require human-mediated translocations to mitigate genetic loss and demographic declines.

Factors that influence rates of mountain lion predation should be examined experimentally to enable managers to better understand this complex system that appears to be substantially altered by anthropogenic causes. Experiments should be designed and conducted in bighorn sheep herds that are large enough to sustain high levels of predation without the need to manipulate mountain lion numbers during the experiment. Understanding the role of alternative prey, including livestock, will be a potential research direction. Understanding the influence of wolf restoration on bighorn sheep and mountain lions, particularly the effect on recruitment of adult female mountain lions, will be important. Because mountain lions are relatively long-lived, this research should be conducted over long periods following the reestablishment of wolves.

MANAGEMENT IMPLICATIONS

Productive bighorn sheep populations are required for restoration via translocation, sport hunting, and endangered species recovery. Management practices to decrease mountain lion densities that adversely affect bighorn sheep populations can be ideally addressed via sport harvest levels regulated by state wildlife agencies. In habitats or states (e.g., CA) where sport harvest does not meet management objectives, facilitated mountain lion control may be required to prevent population declines of bighorn sheep. Removal of resident mountain lions, prior to translocation of desert bighorn sheep, has increased the probability of successful restoration (Rominger et al. 2009).

There is still the potential that bighorn sheep can remain a viable faunal component in the North American west. If the public and wildlife managers are interested in keeping and restoring bighorn to their native ranges for viewing, hunting, and as source populations for recovery in landscapes that have been anthropogenically altered, difficult decisions will have to be made. Continued research on predation and other ecological factors will aid in the conservation of this species.

ACKNOWLEDGMENTS

I thank H. H. Sawyer and F. G. Lindzey for their review of predation and bighorn sheep in 2002, J. L. Davis and J. D. Wehausen for stimulating discussions on California mountain lion and bighorn sheep ecology. V. W. Anglin, J. F. Anglin, A. Ford (deceased), W. D. Glenn, S. C. Harvill, K. Glenn-Kimbrow, and L. D. Lindbeck for their considerable knowledge of lion hunting. A. R. E. Sinclair and V. Geist provided insight on predation. B. D. Brochu provided insight on the high mountain lion predation in the current restoration effort in the Catalina Mountains, Arizona. H. U. Wittmer provided insight on the kleptoparasitism and apparent competition literature. M. C. Chitwood provided insight on the ecological trap literature. R. A. Weaver (deceased), A. V. Sandoval, and R. Valdez provided discussions on desert bighorn sheep ecology. State and provincial biologists that have shared their knowledge include S. B. Bates, V. C. Bleich, C. E. Brewer, T. L. Carlsen, E. F. Cassirer, V. L. Coggins, S. C. Cunningham,

D. L. Heft, H. B. Ernest, C. L. Foster, E. J. Goldstein, F. Hernandez, A. H. Hubbs, M. C. Jorgensen, C. P. Lehman, A. A. Munig, S. M. Murphy, T. D. Nordeen, R. W. Robinson, E. S. Rubin, M. W. Schlegel, T. R. Stephenson, B. A. Sterling, J. C. Whiting, D. T. Wilkins, and F. S. Winslow. K. P. Hurley and the Northern Wild Sheep and Goat Council provided the list-serve to access the cumulative knowledge of biologists associated with bighorn sheep. I also thank M. S. Boyce and P. R. Krausman for initiating this Special Feature of *The Journal of Wildlife Management* and for their editorial acumen. L. G. Adams, J. L. Davis, V. Geist, B. M. Jansen, S. M. Murphy, N. T. Quintana, C. Q. Ruhl, and 2 anonymous reviewers provided their time and comments on previous versions of the manuscript. I acknowledge NMDGF for the dedication to recovering desert bighorn sheep.

Summary

1. To assess recovery of endangered species, reliable information on the size and density of the target population is required. In practice, however, this information has proved hard to acquire, especially for large carnivores that exist at low densities, are cryptic and range widely. Many large carnivore species such as the endangered Florida panther *Puma concolor coryi* lack clear visual features for individual identification; thus, using standard approaches for estimating population size, such as camera-trapping and capture–recapture modelling, has so far not been possible.

2. We developed a spatial capture–recapture model that requires only a portion of the individuals in the population to be identifiable, using data from two 9-month camera-trapping surveys conducted within the core range of panthers in southwestern Florida. Identity of three radio-collared individuals was known, and we incorporated their telemetry location data into the model to improve parameter estimates.

3. The resulting density estimates of 1.51 (± 0.81) and 1.46 (± 0.76) Florida panthers per 100 km² for each year are the first estimates for this endangered subspecies and are consistent with estimates for other puma subspecies.

4. A simulation study showed that estimates of density may exhibit some positive bias but coverage of the true values by 95% credible intervals was nominal.

5. *Synthesis and applications.* This approach provides a framework for monitoring the Florida panther – and other species without conspicuous markings – while fully accounting for imperfect detection and varying sampling effort, issues of fundamental importance in the monitoring of wildlife populations.

Key-words: camera-trapping, mark–resight, population estimation, *Puma concolor coryi*, spatial capture–recapture, telemetry, unmarked populations

Introduction

An accurate understanding of population status is fundamental for the management and recovery of endangered species (Campbell *et al.* 2002; Hoekstra *et al.* 2002). However, estimates of population size and density are lacking for many of the world's most endangered species. As a result, it has been difficult to quantify extinction risk and monitor the effects of conservation actions.

The Florida panther *Puma concolor coryi* is the last remaining puma subspecies in eastern North America. Originally occurring from Arkansas and Louisiana to South Carolina and Florida (Young & Goldman 1946), the current distribution is restricted to about 10 000 km² in southern Florida (Kautz *et al.* 2006). Due to unregulated hunting in the 19th century and large-scale loss of habitat during the 20th century (Onorato *et al.* 2010), Florida panthers were listed as endangered in 1967 (US Federal Register 1967) and subsequently protected under the Endangered Species Act of 1973 (Public Law 93-205).

*Correspondence author. E-mail: rsollma@ncsu.edu

Nevertheless, by the early 1990s, their population had dwindled to 20–30 individuals (McBride *et al.* 2008). Intensive population management, including introduction of wild-caught pumas from Texas to alleviate effects of inbreeding (Seal 1994; USFWS 1994), legal protection (O'Brien & Mayr 1991; Janis & Clark 2002), efforts to reduce road mortality (Foster & Humphrey 1995), and habitat and prey conservation (Janis & Clark 2002) have led to an increase in panther abundance (McBride *et al.* 2008) and genetic diversity (Johnson *et al.* 2010). Still, the Florida panther remains one of the most endangered felids world-wide (Onorato *et al.* 2010).

The Florida Fish and Wildlife Conservation Commission (FWC), with assistance from the federal government (e.g. National Park Service – NPS, U.S. Fish and Wildlife Service – USFWS), commenced research on the Florida panther in 1981, resulting in publications covering a variety of topics including: estimates of demographic parameters, habitat selection, assessment of genetic restoration and documentation of biomedical issues (Beier *et al.* 2003; Onorato *et al.* 2010). Despite the intensive research effort, producing rigorous estimates of population size for the Florida panther has eluded scientists for decades (Beier *et al.* 2003), yet abundance remains a central tenet of the USFWS recovery plan objectives (USFWS 2008).

Large, elusive carnivores such as pumas are typically difficult to sample, and accurate estimates of population-related parameters are often challenging to obtain. Obstacles include low sample sizes due to rarity, wide-ranging behaviour and concerns about invasive sampling methods. Mark–recapture techniques are generally considered the gold standard for generating robust estimates of population parameters. For many felid species, camera-trapping is increasingly used for abundance estimates because the technique is non-invasive and efficient. The resulting data, in combination with traditional capture–recapture (CR) models (e.g. Otis *et al.* 1978) or spatial capture–recapture (SCR) models (e.g. Efford 2004; Royle & Young 2008), have largely facilitated the estimation of demographic parameters of many felid species with unique pelage patterns (e.g. Karanth & Nichols 1998; Karanth *et al.* 2006; Royle *et al.* 2009). Although some puma studies use this combination of methods (Kelly *et al.* 2008; Negrões *et al.* 2010), the species generally lacks clear features for individual identification from photographs, seemingly rendering camera-trapping an unfeasible option for capture–recapture modelling of Florida panthers.

Alternatively, scat sampling in combination with genetic analyses can provide capture–recapture data (Royle, Kéry & Guélat 2011). Although this sampling technique has been applied in the study of felid populations (e.g. Ruell *et al.* 2009; Gopalaswamy *et al.* 2012), it would be difficult to implement for the Florida panther due to the subspecies' low genetic diversity (Roelke, Martenson & O'Brien 1993) and the fast decay of DNA in Florida's

warm and moist climate (Farrell, Roman & Sunquist 2000; Lucchini *et al.* 2002).

Given the obstacle of individual identification, collecting capture–recapture data would require that animals be physically marked and recaptured. The high cost and safety issues to both animal and handler make such approaches impractical for elusive and potentially dangerous animals like large carnivores. This risk is compounded when dealing with the small populations of endangered species. Thus, non-invasive sampling techniques are preferable whenever possible (Long *et al.* 2008).

Florida panthers have been extensively studied using traditional very high frequency (VHF) and Global Positioning System (GPS) telemetry (e.g. Land *et al.* 2008; Onorato *et al.* 2011). Potentially, telemetry collars permit individual identification based on collar characteristics (e.g. different brands on different individuals or modifying collars with unique marks) observable in photographs. Under these circumstances, camera-trap surveys concurrent with existing telemetry studies can provide data suitable for population estimation in the framework of mark–resight models (e.g. Rice & Harder 1977; McClintock *et al.* 2009; McClintock & White 2010), which do not require that individuals be physically captured multiple times. Rather, a sample of individuals is captured and marked during a single marking event that occurs prior to resighting surveys, and a non-invasive technique such as camera-trapping or visual resighting can be used to collect 'recapture' data on these individuals. While mark–resight models provide robust estimates of abundance, they suffer from the same shortcomings as traditional capture–recapture models when it comes to estimating population density. To estimate density, we need to define the area sampled. This generally relies on ad-hoc approaches, which renders density estimates somewhat arbitrary.

Our objective was to provide a rigorous and statistically sound density estimate for Florida panthers in the Pica-yune Strand Restoration Project area (PSRP). We used data collected during a 21-month camera-trapping study (Shindle & Kelly 2007) and telemetry data simultaneously collected by the FWC in a new modelling framework that, analogous to traditional mark–resight, allows for only a portion of the population to be identified (Chandler & Royle *In Press*; Sollmann *et al.* 2013). Further, analogous to SCR models, this new framework explicitly links abundance to a clearly defined area, thus providing unambiguous density estimates. To improve the estimation of model parameters associated with individual location and movement, and to produce more precise estimates of density, we extend the model by also incorporating telemetry location data. We confirm the reliability of model results using a simulation study. Providing a rigorous estimate of Florida panther density, this modelling approach has wide application for animal conservation and endangered species management.

Materials and methods

STUDY AREA

The study was conducted in PSRP, an area that encompasses the former Southern Golden Gate Estates subdivision development, covering approximately 241 km² in Collier County, Florida. Originally slated for housing development, the area is currently undergoing vegetative and hydrological restoration (U.S. Army Corps of Engineers 2004). Together with two neighbouring reserves, the PSRP forms a large block of panther habitat in the core of the subspecies' range. The climate of the study area is that of a tropical savannah with distinct wet (May–October) and dry (November–April) seasons (Duever *et al.* 1985).

CAMERA-TRAPPING AND RADIOTELEMETRY

From 2005 to 2007, 98 camera traps (Digital CamTrakkerTM, CamTrak South Inc., Watkinsville, GA, USA) with passive infrared heat-in-motion detectors were deployed in PSRP for 21 consecutive months as part of a pre-restoration baseline survey for panther and white-tailed deer *Odocoileus virginianus* (Shindle & Kelly 2007). A grid with 2-km² cells was overlaid on the study area, and one camera was placed within each grid cell (Fig. 1). Most cameras were deployed along roads or trails and secured to trees approximately 45 cm above ground. Cameras operated 24 h per day with a minimum 20-s delay between sequential photographs. Camera traps were checked every 21–28 days to retrieve images and ensure units were functioning.

Fig. 1. Picayune Strand Restoration Project area, Southern Florida, with camera-trapping grid used to survey Florida panthers between 2005 and 2007, and radiotelemetry locations for three collared panthers (stars, circles and triangles) used in the spatial mark–resight model as the marked portion of the population.

The FWC monitors Florida panthers in the PSRP and neighbouring areas using radiotelemetry. Locations were collected via aerial telemetry three times per week (see Land *et al.* (2008) for methods). Manufacturers of radiocollars included Telonics (Mesa, Arizona, USA), Advanced Telemetry Systems (Isanti, MN, USA) and Followit (Lindesberg, Sweden). Collars from different manufacturers have distinct physical features and therefore provided a visual means of individual identification of collared panthers from camera-trap pictures.

Mark–resight models require that all marking takes place before resighting. Here, we regard those panthers as the marked part of our population that wore radiocollars throughout one or both primary camera-trapping occasions (see below) and used the PSRP as part of their home range. Panthers that were collared during the course of a primary occasion were regarded as ‘unmarked’. Although some photographs of uncollared panthers could be attributed to individuals based on natural marks, many photographs of uncollared panthers were ambiguous. Since mark–resight models require that individuals can always correctly be identified as marked or unmarked, we treated all photographs of uncollared individuals as unmarked. For photographic records of uncollared individuals, we treated subsequent pictures at a given camera trap as independent if they were separated by at least an hour. Photographs that showed two (three, etc.) individuals were treated as two (three, etc.) independent records. We discarded pictures that we were unable to verify whether the individual was collared or not. We further excluded dependent kittens and juveniles from our analysis.

DATA ANALYSIS

Spatial capture–recapture models

We analysed concurrent photographic and telemetry data, building on the SCR model for partially marked populations described by Chandler & Royle (In press). Generally, SCR combines a model for individual location and movement with a model describing detection by traps, using individual and site specific detection data (Borchers & Efford 2008; Royle & Young 2008; Gardner, Royle & Wegan 2009; Borchers 2012). In SCR models, we assume that each individual i has an activity centre, s_i , and that all s_i are distributed uniformly across the state space S , an area including the trapping grid, chosen large enough to include all animals potentially exposed to sampling. We assume that the number of records of individual i at trap j and occasion k , y_{ijk} , is a Poisson random variable with mean encounter rate λ_{ij} , which is a decreasing function of the distance, d_{ij} , from trap j to the individual's activity centre s_i . Under a half-normal encounter rate model,

$$\lambda_{ij} = \lambda_0 * \exp(-d_{ij}^2 / 2\sigma^2),$$

λ_0 is the baseline trap encounter rate at $d_{ij} = 0$ and σ is the scale parameter of the half-normal function.

To estimate N , the number of activity centres in S , we employ data augmentation (Royle, Dorazio & Link 2007). Let n be the number of observed individuals. Then this approach is equivalent to augmenting the observed data set with $M - n$ ‘all-zero’ encounter histories or ‘hypothetical individuals’ that were never observed. N is estimated as the sum of an individual auxiliary variable, z_i ,

$z_i \sim \text{Bernoulli}(\Psi)$

where $i = 1, 2, 3, \dots, M$ and $z_i = 1$ if the animal is part of the population and 0 otherwise. The prior probability of Ψ is uniform (0,1), which corresponds to a discrete uniform (0, M) prior probability for N . M is an arbitrary value set sufficiently large as to not truncate estimates of N . Density, D , can be derived by dividing N by the area of S .

Extension of the SCR model to a mark-resight situation

Chandler & Royle (In press) extended this model to a mark-resight situation, where only part of the population can be individually identified. Under these circumstances, the individual encounter histories y_{ijk} are partially latent – only y_{ijk} for the m marked animals are observed. For the unmarked individuals, we observe only the accumulated counts $n_{jk} = \sum \mathbf{y}_{ujk}$, where $\mathbf{u} = \{m + 1, \dots, N\}$ is an index vector of the $N - m = U$ unmarked individuals. Unobserved encounter histories are essentially missing data. Adopting a Bayesian framework and using Metropolis-within-Gibbs (MwG) Markov chain Monte Carlo (MCMC) sampling, we can update missing data using their full conditional distribution (Gelman *et al.* 2004, Ch. 11). For the y_{ijk} from unmarked animals, the full conditional is multinomial with sample size n_{jk} :

$$\mathbf{y}_{ujk} \sim \text{Multinomial}(n_{jk}, \lambda_{uj} / \sum \lambda_{uj})$$

The remaining model parameters are then updated conditional on the full set of encounter histories.

When the number of marked individuals, m , is known, estimating N reduces to estimating the number of unmarked individuals U . In this situation, $M - m = \text{size of the hypothetical unmarked population in } S$. By updating the latent encounter histories (see above), we assign records of unmarked individuals to some of these hypothetical individuals, so that their encounter histories are no longer ‘all-zero’.

In non-spatial mark-resight models, an important model assumption is that marked individuals represent a random subset of the population. This assumption is still required in spatial mark-resight, but additionally, the marked individuals must represent a random sample of individuals in the state space S . Here, we have only a small set of marked individuals (see results), and the telemetry information for these individuals indicates that they are distributed throughout most of S (Fig. 1).

Incorporating telemetry location data

We can relate the parameters of the half-normal encounter rate model to those of a bivariate normal movement model (Calhoun & Casby 1958), with mean = \mathbf{s}_i , and variance-covariance matrix Σ , where the variance in both dimensions is σ^2 and covariance is 0. Under this model, σ can be related to a measure of how far individuals move (Reppucci, Gardner & Lucherini 2011). Ordinarily, these parameters are estimated only from the trapping data. Telemetry data, however, provide more detailed information on individual location and movement. By assuming that the R_i locations of individual i , \mathbf{l}_i , are a bivariate normal (Normal_2) random variable:

$$\mathbf{l}_i \sim \text{Normal}_2(\mathbf{s}_i, \Sigma)$$

we can estimate σ , as well as \mathbf{s}_i for the collared individuals, directly from telemetry location data using their full conditional

distributions within the MwG sampler. Under this formulation, σ and \mathbf{s}_i for the collared individuals are no longer conditional on the resighting data \mathbf{y} , but only on \mathbf{l} . For the unmarked individuals, \mathbf{s}_i are estimated as in conventional SCR, conditional on the encounter histories. The full MwG MCMC sampler can be found in Appendix S1 (Supporting Information).

Model application to Florida panther data

To account for the lack of demographic population closure over 21 months of camera-trapping, we defined two primary occasions, from 1 July 2005 to 31 March 2006 and from 1 July 2006 to 31 March 2007. Within primary occasions, we grouped data by month and accounted for the number of days each camera trap was functional each month, t_{jk} , using $\lambda_{ij} * t_{jk}/30$. We limited telemetry data used in our model to the same time periods. To define S , we used a 15-km buffer from the outermost coordinates of the trapping grid and removed parts of the resulting rectangle that comprised ocean or islands. This resulted in an area for S of 1719.13 km².

We ran three chains of the MwG sampler with 200 000 iterations each, discarding 10 000 iterations as burn-in using the software R 2.13.0 (R Development Core Team 2011). To check for chain convergence, we calculated the Gelman-Rubin statistic R-hat (Gelman *et al.* 2004) using the R package coda (Plummer *et al.* 2006). Values below 1.1 indicate convergence; in our results, all model parameters had R-hat < 1.1. We report the posterior mean (\pm standard deviation), mode, and 95% Bayesian credible intervals (95BCI) for all parameters.

Results

During the two primary occasions, we accumulated 43 890 trap days and obtained 445 photographs of Florida panthers. We discarded 137 pictures that we were unable to determine whether they belonged to a radio-collared individual or not and one picture of a collared panther that traversed the study area but was not resident (see Discussion for further treatment of this topic). Of the remaining photographs, 17 were records of identifiable radio-collared individuals and 290 pictures showed uncollared panthers (Table 1).

Three individuals met our requirements of being collared throughout one or both primary sampling occasions, with two collared individuals being present in one primary occasion only, while one was present in both occasions. For each collared individual, we accumulated an average

Table 1. Collared Florida panthers present in the Picayune Strand Restoration Project area and used as marked individuals in the spatial mark-resight model, total number of photographs and number of photographic records of these collared individuals in the two 9-month primary camera-trapping occasions

Occasion	No. collared individuals	Total number of pictures	No. pictures of collared individuals
1	2	131	2
2	2	176	15
Total*	3	307	17

*One individual from year 1 was present again in year 2.

of 99.5 (SD 10.6) telemetry locations per primary occasion (Fig. 1).

The posterior mean for the movement parameter σ was 4.45 (± 0.11) km. The baseline trap encounter rate λ_0 had a posterior mean of 0.09 (± 0.02) expected photographs per 30 days. The posterior mean for population density D was 1.63 (± 0.50) individuals per 100 km² in year 1 and 1.66 (± 0.56) individuals per 100 km² in year 2; for both years, the posterior mode was slightly lower, at 1.51 and 1.46 individuals per 100 km², respectively. Posterior summaries of parameter estimates are given in Table 2.

SIMULATION STUDY

To investigate potential bias and precision of our estimators, we generated 100 data sets consisting of both camera detection and telemetry location data under the same conditions observed for the surveyed panthers (i.e. with parameters equal to the posterior means obtained in our analyses, and the trapping grid, sampling effort, number of known individuals and telemetry locations equivalent to values in the actual field study). Across 100 data sets, parameters were estimated with low accuracy (relative root mean squared error (RMSE) 26–39%); only the RMSE of σ was low, at 3%. For N , the posterior mode presented a less biased estimator (relative bias 11–13%) than the mean (27–29%). For λ_0 and σ , relative bias of the mean was 4 and 0.3%, respectively. Coverage of the true values by 95% BCI was between 92% and 99% for all parameters (see Appendix S2, Supporting Information).

Discussion

Large felids such as the Florida panther are notoriously difficult to monitor. Low population densities and elusive behaviour often result in sparse data, requiring intensive sampling over several years. Camera traps are an ideal tool for the study of large and wide-ranging species, but

inference from camera-trap data for populations that cannot be individually identified is limited. Mark–resight methods have long been used as an alternative to traditional mark–recapture studies (e.g. Rice & Harder 1977; Minta & Mangel 1989), but only recently has the concept of mark–resight modelling been extended to SCR models (Chandler & Royle In press). This development has made it possible to address a major problem facing wildlife managers who are in need of reliable density estimates for rare and elusive species without conspicuous natural marks.

FLORIDA PANTHER DENSITY

The density estimates of approximately 1.5 individuals per 100 km² summarize the current state of knowledge on Florida panthers in PSRP. Historically, there have been no reliable estimates of abundance or density for the Florida panther (Beier *et al.* 2003). Although the density estimate by Maehr, Land & Roof (1991) of one individual in 110 km² was considered reasonable, it lacked confidence intervals and could not be applied elsewhere (Beier *et al.* 2003). Similarly, counts based on physical evidence (e.g. tracks, scats; McBride *et al.* 2008) do not account for varying sampling effort, possible double-counting of or failure to detect individuals, and they lack the potential for repeatability due to a reliance on expert observers for accurate interpretation of panther signs.

Our density estimates fall within reported densities of pumas in other parts of their geographical range. Generally, the lowest puma densities of ≤ 1 individual per 100 km² are found in the northern part of the species' range (e.g. Hemker, Lindzey & Ackerman 1984; Laundré & Clark 2003). Except for areas heavily impacted by poaching and logging, Central and South America generally harbour higher puma densities, ranging from just over 1 to almost 7 individuals per 100 km² (Kelly *et al.* 2008; Paviolo *et al.* 2009; Negrões *et al.* 2010; Soria-Diaz *et al.* 2010). Given the tropical climate and habitat of Florida, and the fact that PSRP is still recovering from heavy anthropogenic impacts, our density estimates of approximately 1.5 panthers per 100 km² are consistent with previous findings.

The panther population of PSRP most likely declined because of the severe habitat degradation caused by water management practices and direct human disturbance. However, PSRP has two neighbouring reserves, the Florida Panther National Wildlife Refuge (FPNWR) and the Fakahatchee Strand Preserve State Park, both of which have been protected for several decades. Compared with these reserves, PSRP probably has less suitable habitat. Indeed, until recently, the PSRP area was mainly used by dispersing male Florida panthers, and reproductive events in the area were rare (Shindle & Kelly 2007). Applying the bivariate normal model to telemetry data from VHF and GPS collared individuals in the neighbouring FPNWR showed that individuals at this site have smaller home ranges (average σ

Table 2. Posterior summaries of parameter estimates from a spatial mark–resight model applied to Florida panther camera-trapping and telemetry data from the Picayune Strand Restoration Project area, Florida. Density is estimated for two 9-month primary occasions (t)

Parameter	Unit	Mean (SE)	Mode	2.5%	97.5%
σ	km	4.45 (0.11)	4.46	4.24	4.68
λ_0	Pictures per 30 days	0.09 (0.02)	0.09	0.06	0.14
$N(t = 1)$	individuals in S	27.98 (8.54)	25	14	47
$N(t = 2)$	individuals in S	28.59 (9.67)	25	13	51
$D(t = 1)$	individuals per 100 km ²	1.63 (0.50)	1.51	0.81	2.73
$D(t = 2)$	individuals per 100 km ²	1.66 (0.56)	1.46	0.76	2.97

was 3.44 km based on seven individuals), which in carnivore populations is often linked to a higher population density (e.g. Dahle & Swenson 2003; Benson, Chamberlain & Leopold 2006). Most likely, individuals from neighbouring reserves are immigrating into the PSRP area as it recovers from the severe anthropogenic impacts and as panther populations in the neighbouring areas expand.

RELIABILITY OF ESTIMATES

The precision of density estimates from spatial mark–resight models depends on the number of marked individuals (Chandler & Royle *In press*). In the present study, photographic data on the small number of radio-collared individuals were particularly sparse (17 pictures total), but incorporating telemetry information about individual locations and movements increased the precision of our density estimate. According to our simulation study, although we can expect some positive small-sample bias in estimates of N , we also expect the true value to fall within the 95BCI. As a result, our modelling framework represents a promising tool for population monitoring of far-ranging, elusive species. For species that are studied extensively using radiotelemetry (Land *et al.* 2008; Onorato *et al.* 2011), the combination of traditional sampling techniques such as radiotelemetry with the increasingly popular methods of camera traps and SCR modelling (Royle *et al.* 2009) is likely to replace more traditional inference methods (Nichols, O'Connell & Karanth 2011). This approach is not limited to Florida panthers, but applies to other species that are not 'naturally marked' but can be tagged or otherwise recognized, and can also be applied to other types of spatial resighting data, such as point counts for birds or amphibians. With adequate sample size, telemetry locations are not necessary to estimate population size, so tags can be anything that permits identification.

Current spatial mark–resight models assume that marked individuals are a random sample from the total population of S . This means, ideally, defining S should be part of the study design and marking efforts should be spread evenly within S . In practice, that may often not be realistic. When marked individuals are not a random sample of S , but were taken from a smaller area, density estimates are likely negatively biased. Relaxing this assumption is the focus of current SMR model development.

IMPLICATIONS FOR FUTURE FLORIDA PANTHER RESEARCH

Despite the progress made towards recovery in over 30 years of research, the Florida panther population continues to require close monitoring. Our method is an improvement over monitoring methods historically implemented for three main reasons:

1. Our model enables researchers to use camera traps, which allow for non-invasive monitoring of Florida

panthers in regions where they are also monitored by telemetry.

2. The spatial mark–resight model provides a standardized analytical framework that accounts for imperfect individual detection and varying sampling effort, so that estimates of density across time and space are comparable.

3. Our modelling approach provides estimates of uncertainty about density estimates. As such, we can fully assess whether a sampling design is yielding appropriate data to monitor the Florida panther population or whether sampling has to be modified (in terms of sampling technique, design and effort).

Still, there is room for improvement. A basic assumption of any mark–resight approach is that the marked individuals are a representative sample of the population (McClintock & White 2010). This is generally accomplished by applying a technique that is different from the resighting method to mark a random sample of individuals (Bowden & Kufeld 1995). While the methods for marking and resighting were distinct in the present study, the extremely low number of collared individuals may not be representative of the entire population. Considering the difficulties, risks and costs associated with capturing large felids, tagging a larger sample of panthers may be challenging. But even adequate coordination of marking and resighting would be an improvement. In the present study, marking and resighting occurred concurrently and individuals tagged within the primary camera-trapping occasions had to be treated as 'uncollared'. By tagging animals ahead of the resight surveys, this loss of valuable data could be avoided.

Owing to the low number of collared individuals, we were unable to incorporate sex- or year-specific differences in movement and detection into our model. Differences in these parameters between males and females are known to be pronounced for large carnivores (e.g. Gardner *et al.* 2010; Sollmann *et al.* 2011). For Florida panthers, males are known to have larger home ranges than females (Onorato *et al.* 2010). Further, collared individuals were photographed more frequently during the second primary occasion, which could indicate higher trap encounter rates. Ideally, future studies should aim at collecting enough data to allow for the modelling of these effects.

The sparseness of the data also precluded any formal treatment of transiency. Transiency is a common issue in open population capture–recapture studies (e.g. Pradel *et al.* 1997). In closed population studies, formally, the presence of transient individuals violates the fundamental assumption of population closure and is therefore generally not explicitly addressed but 'assumed away'. Only because we had radiotelemetry locations, we were able to identify one of the collared panthers in our study as a transient and we decided to remove that individual from the data set. We cannot apply such a correction to the uncollared individuals. By removing transients from the collared individuals but not the uncollared, the former are arguably no longer a representative sample of the latter, which may introduce some positive bias into the estimates of density. We found,

however, that retaining the transient individual resulted in unreasonable estimates of the movement parameter σ (data not shown). Given the transient's large movements this is not surprising: when applying the bivariate normal movement model to individual sets of telemetry locations, σ for the transient was 3.5 times larger than for the remaining individuals. Within the spatial mark–resight model, the estimate of σ almost doubled when retaining the transient. While it is disconcerting that a single individual impacted estimates to such a degree, this is a consequence of the small data set, where one outlier has disproportionate effects on model outcomes. With an adequate sample size (i.e. larger number of marked individuals), presence of a single outlier would have a much smaller impact. Further, the problem could be avoided or diminished by shortening the sampling time frame to better approximate a closed population. Even if a transient is present, over a short time interval, its movements are unlikely to be so pronouncedly different from resident individuals, thus diminishing its effect on parameter estimates. Alternatively, with adequate sample size, or as information on the proportion of transients in the population accumulates over time, transiency could be addressed explicitly within the model, for example, using an individual covariate describing transiency state. Regardless of the approach, future study design for Florida panther population monitoring has to both strive for larger sample sizes and consider the assumption of population closure.

Finally, identifiability of individuals on pictures could be improved, for example, by increasing camera trigger speed to allow more centred subjects and by taking multiple pictures per camera-trapping event. We discarded 137 pictures from analysis because we were unable to tell whether an animal was wearing a collar or not. If individuals can at least be identified as 'marked' (but not to individual level), their data can still be included in mark–resight models (e.g. McClintock *et al.* 2009; Sollmann *et al.* 2013).

In spite of these caveats, spatial mark–resight models allow for the development of a standardized protocol that can be applied by different investigators and at different study sites without compromising the comparability of results. As such, these models provide a valuable population monitoring tool for wildlife species that are not consistently identifiable to the individual level. For Florida panthers, spatial mark–resight models could be the cornerstone of a distribution-wide survey protocol to estimate the density or size of the Florida panther population. This is a current research priority and will be indispensable in helping quantify the level of success conservation, and management measures are having at achieving recovery objectives outlined by the USFWS.

Acknowledgements

We thank the U. S. Fish and Wildlife Service, U. S. Army Corps of Engineers, and U. S. Geological Survey for financial support and the North Carolina Cooperative Fish and Wildlife Research Unit for

assistance with funding administration. We thank two anonymous reviewers and the editor Paul Lukacs for helpful comments on earlier drafts of this manuscript. In addition, we thank the citizens of Florida that support panther conservation via the purchase of 'Protect the Panther' licence plates. The FWC data used in this project were collected using revenue accrued from the purchase of these plates.

Abstract

Currently, 11 western states and 2 Canadian provinces use sport hunting as the primary mechanism for managing cougar (*Puma concolor*) populations. Yet the impacts of sustained harvest on cougar population dynamics and demographic structure are not well understood. We evaluated the effects of hunting on cougar populations by comparing the dynamics and demographic composition of 2 populations exposed to different levels of harvest. We monitored the cougar populations on Monroe Mountain in south-central Utah, USA, and in the Oquirrh Mountains of north-central Utah from 1996 to 2004. Over this interval the Monroe population was subjected to annual removals ranging from 17.6–51.5% (mean \pm SE = 35.4 \pm 4.3%) of the population, resulting in a >60% decline in cougar population density. Concurrently, the Oquirrh study area was closed to hunting and the population remained stationary. Mean age in the hunted population was lower than in the protected population ($F = 9.0$; $df = 1, 60.3$; $P = 0.004$), and in a pooled sample of all study animals, females were older than males ($F = 13.8$; $df = 1, 60.3$; $P < 0.001$). Females from the hunted population were significantly younger than those from the protected population (3.7 vs. 5.9 yr), whereas male ages did not differ between sites (3.1 vs. 3.4 yr), suggesting that male spatial requirements may put a lower limit on the area necessary to protect a subpopulation. Survival tracked trends in density on both sites. Levels of human-caused mortality were significantly different between sites ($\chi^2 = 7.5$; $P = 0.006$). Fecundity rates were highly variable in the protected population but appeared to track density trends with a 1-year lag on the hunted site. Results indicate that harvest exceeding 40% of the population, sustained for ≥ 4 years, can have significant impacts on cougar population dynamics and demographic composition. Patterns of recruitment resembled a source-sink population structure due in part to spatially variable management strategies. Based on these observations, the temporal scale of population recovery will most likely be a function of local harvest levels, the productivity of potential source populations, and the degree of landscape connectivity among demes. Under these conditions the metapopulation perspective holds promise for broad-scale management of this species. (JOURNAL OF WILDLIFE MANAGEMENT 70(6):1588–1600; 2006)

Key words

connectivity, cougar, demographics, hunting, metapopulation, population dynamics, *Puma concolor*, radiotelemetry, refuge, source-sink dynamics, Utah.

Across western North America sport harvest is the primary mechanism for the population-scale management of *Puma concolor* (Pierce and Bleich 2003). Management regimes vary from public safety and depredation control only in California, to a year-round open season in Texas (Nowell and Jackson 1996). In order to balance hunting opportunities with protection of big game and livestock, most states manage cougar populations at some intermediate level. However, cougars are secretive, long-lived, and utilize large home ranges, making them difficult to manage with precision (Ross et al. 1996). At present, there are no widely accepted methods for the enumeration of cougars across diverse habitat types and climatic regimes (Anderson et al. 1992, Ross et al. 1996). Most techniques (e.g., track counts, scent stations, probability sampling) have limitations that render them marginally useful (Choate et al. 2006) or capable of detecting only large and rapid changes in population size (Van Sickle and Lindzey 1992, Beier and

Cunningham 1996). Additionally, cougars occur at low population densities relative to their primary prey, making them sensitive both to bottom-up (e.g., prey declines; Logan and Sweaner 2001, Bowyer et al. 2005) and top-down (e.g., overexploitation; Murphy 1998) perturbations. Assessing cougar population trends is complicated by annual removals of varying intensity. Changes in population size and composition are generally indexed through harvest data and are therefore confounded by nonrandom sampling biases, further hindering reliable trend estimation (Wolfe et al. 2004).

Cougar management in Utah is spatially organized, with 4 broad ecoregions subdivided into 30 different hunting units. Each unit is managed independently in order to apply harvest pressure according to local priorities, which can include density reductions aimed at increasing survival in mule deer (*Odocoileus hemionus*) or bighorn sheep (*Ovis canadensis*) populations. Cougars are therefore managed at 2 different spatial scales. Locally, they are either managed conservatively as a trophy species or liberally as a limiting factor in the population dynamics of native ungulates. The statewide population, however, is managed for sustainable

² Present address: Department of Biological Sciences, University of Notre Dame, Notre Dame, IN 46556 USA

hunting opportunities and persistence across its currently occupied range (Mason et al. 1999).

Cougar hunting in Utah is conducted by means of pursuit with trained hounds. The hunting season extends from mid-December to early June, but approximately 75% of the kill occurs during December to March, when snow cover facilitates tracking and pursuit (Mason et al. 1999). Prior to 1998 the sport harvest of cougars occurred under a Limited Entry (i.e., lottery) system in which the number of permits for individual units is restricted. The long-term mean hunter success for this system is 64%. Beginning with the 1997–1998 season the Harvest Objective (i.e., quota) system was introduced for some units. This system employs an unlimited availability of permits to achieve a prescribed level of kill. Hunters are required to report their kill within 48 hours and the unit is closed once the quota is reached. Typically 74% of the quota is achieved, but instances of overharvest do occur. Between 1995 and 2003 legal harvest accounted for 90.0% of the total statewide cougar kill (Hill and Bunnell 2005). The remaining known mortality was distributed among animals killed in response to livestock depredation (6.2%) and other human-caused mortality, including roadkill and accidental trappings (3.8%). Additional unreported mortality such as incidental take during big game hunting seasons and illegal snaring occurs, but the magnitude of this impact is probably small relative to legal harvest. Individual cougars involved in livestock depredation are managed by the Wildlife Services Division of the United States Department of Agriculture, who may employ foot-hold snares as well as hounds to remove offending individuals. Nuisance cougars are defined as animals in urban settings that constitute a potential threat to human safety. These animals are generally controlled by Utah Division of Wildlife Resources (UDWR) personnel using lethal or nonlethal means, as circumstances warrant.

Little is known about both the immediate and long-term effects of sustained harvest on cougar populations (Anderson 1983, Ross et al. 1996). Numerous studies have been conducted on exploited populations (Murphy 1983, Barnhurst 1986, Logan et al. 1986, Ross and Jalkotzy 1992, Cunningham et al. 2000), including 2 removal experiments (Lindzey et al. 1992, Logan and Sweanor 2001), but few of these studies directly addressed the questions of: 1) how harvest affects the demographic structure of a population, and 2) what the long-term implications are for persistence and recovery of exploited populations within a metapopulation context. Moreover, habitat configuration and connectivity are important factors influencing cougar recruitment patterns, but with few exceptions (Beier 1993, 1995, Maehr et al. 2002) this relationship has been largely overlooked.

Recent years have seen the emergence of the idea of managing cougars as a metapopulation based on the effects of natural habitat patchiness (Sweanor et al. 2000, Laundré and Clark 2003) or anthropogenic fragmentation (Beier 1996, Ernest et al. 2003). Because metapopulations transcend administrative boundaries, understanding population

response to sustained harvest is vital in order to manage for persistence across landscapes exhibiting varying degrees of natural and human-caused fragmentation.

We assessed the impacts of exploitation on cougar population dynamics by comparing demographic characteristics between an exploited and a semiprotected population. Specific objectives of this study were: 1) determine how harvest levels might influence the dynamics and demographic structure of individual populations, 2) identify the factors that may influence the rate of population recovery, and 3) assess how the distribution of harvest impacts might affect recruitment within a metapopulation context.

Study Area

Cougar habitat in Utah is geographically fragmented, being broadly associated with mesic regions between 1500 m and 3000 m. The Wasatch Mountains and associated high plateaus form the core habitat, longitudinally bisecting the state, whereas the Colorado Plateau and Great Basin ecoregions consist primarily of desert ecosystems, with suitable habitat sparsely distributed among insular mountain ranges (Fig. 1). We selected Monroe Mountain and the Oquirrh Mountains as study areas for this research (Fig. 1). Although differences existed between these sites in terms of size and plant community composition, they were located within 190 km of each other, making them climatically and ecologically similar in a broad sense, but far enough apart to be treated demographically as independent populations. The most pronounced difference between these populations was the level of exploitation to which each was subjected.

Exploited Area

Monroe Mountain comprises part of the Sevier Plateau in the Southern Mountains ecoregion of south-central Utah (38.5°N, 112°W). The site is a high volcanic plateau extending 75 km in a north–south orientation and lies within a west–east geologic transition from basin and range topography to the Colorado Plateau. Hydrologically, Monroe is part of the Great Basin, but climatically and biologically it is more closely associated with other high-elevation regions of the Colorado Plateau and southern Rocky Mountains. The study site covered approximately 1,300 km² and encompassed the central unit of the Fishlake National Forest, southeast of Richfield. Other landholders included the Bureau of Land Management (BLM), State of Utah, and various private interests.

The terrain is mountainous with elevations ranging from 1,600–3,400 m. Annual precipitation ranged from 15–20 cm at lower elevations to 60–120 cm on the plateaus above 2,700 m. Approximately 60% of the annual precipitation occurred as snow in January and February, with most of the remainder derived from summer thunderstorms (Ashcroft et al. 1992). Snowpack typically persisted until mid-June at elevations >3,000 m. Mean monthly temperatures ranged from –4.6° C in January to 18.7° C in July (Ashcroft et al. 1992).

Plant communities were diverse and varied with elevation and aspect (Edwards et al. 1995). Piñon-juniper woodlands

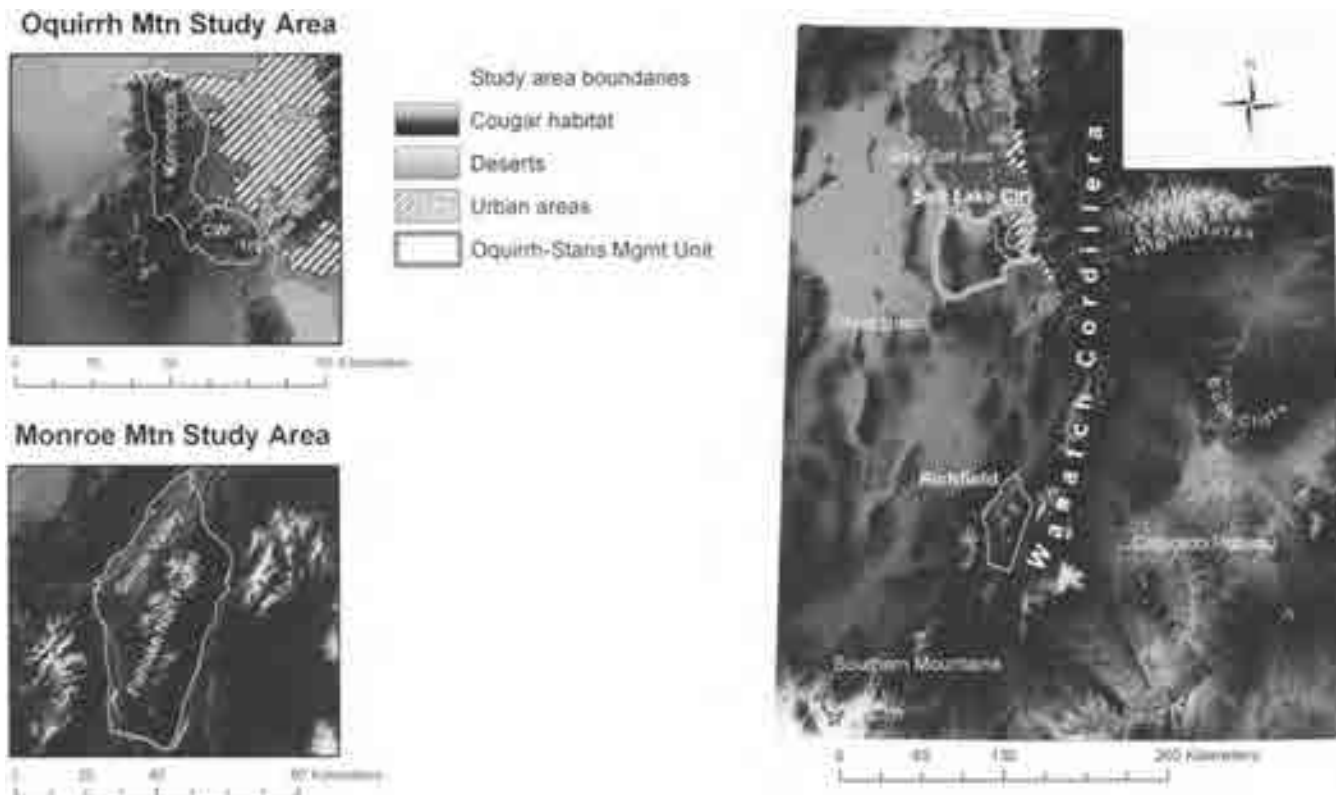

Figure 1. Study-area locations and cougar habitat across Utah, USA, 1996–2004.

(*Pinus edulis*, *Juniperus scopulorum*, *Juniperus osteosperma*) comprised the single largest vegetation type covering approximately 44% of the area. Mixed conifer and aspen (*Populus tremuloides*) stands occurred at higher elevations, with gambel oak (*Quercus gambelii*), mountain shrub (e.g., *Cercocarpus ledifolius*, *Rosa woodsii*, *Purshia tridentata*), and mixed sagebrush (*Artemisia tridentata*)–grassland meadows interspersed throughout.

Resource exploitation included livestock grazing, logging, and recreation. The UDWR classified Monroe Mountain as Cougar Management Unit 23. Mule deer and elk (*Cervus elaphus*), the primary cougar prey species on this site, were also managed for annual harvests. Human densities around the site varied from 73/100 km² to 382/100 km² (U.S. Census Bureau), with most of the population scattered among small agricultural communities in the Sevier Valley on the northwestern boundary of the study site.

Protected Area

The Oquirrh-Traverse Mountains complex (hereafter the Oquirrhs) extends 55 km in a north–south orientation on the eastern edge of the Great Basin ecoregion in north-central Utah (40.5°N, 112.2°W). The Oquirrhs are typical of other mountain ranges within this ecoregion in that they form islands of high productivity relative to the surrounding desert basins (Brown 1971) and thus represented the majority of cougar habitat in this area.

The total area of the Oquirrhs measures approximately 950 km², but we conducted fieldwork primarily on the northeastern slope of the range on properties owned and

managed by the Utah Army National Guard (Camp Williams, Traverse Mountains, 100 km²) and the Kennecott Utah Copper Corporation (Oquirrh Mountains, 380 km²). The site was situated at the southern end of the Great Salt Lake, abutting the southwestern side of the greater Salt Lake metro area. Ownership on the southern and western portions of the Oquirrhs was a conglomeration of BLM, grazing associations, and small mining interests, with approximately 45% of the range residing in private ownership.

Elevations on the site vary from lake level at 1,280 m up to 3,200 m. The Traverse Mountains run perpendicular to the Oquirrhs, and range in elevation from 1,650 m to 2,100 m. Annual precipitation ranged from 30–40 cm in the Salt Lake and Tooele valleys to 100–130 cm on the highest ridges and peaks. Most precipitation fell as snow between December and April, with approximately 25% occurring in the form of summer thunderstorms. Mean monthly temperatures ranged from −2.4° C in January to 22.2° C in July (Ashcroft et al. 1992).

Gambel oak and sagebrush were the predominant vegetation on the site. Also prevalent were Utah juniper in the foothills, and canyon maple (*Acer grandidentatum*) in the drainages at low elevations, and across broader areas above 1,800 m. Mountain mahogany (*Cercocarpus spp.*) was present, but relegated to well-drained soils along ridges. North-facing slopes above 2,200 m supported localized montane communities of aspen and Douglas fir (Edwards et al. 1995).

Mining activities have dominated the Kennecott property

for >100 years (Roylance 1982), and the site included 2 large open pit mines and attendant infrastructure. Camp Williams was used for military training activities, and consequently exhibited brief fire return intervals. All prominent peaks on the study site supported commercial radio and television transmitters with associated access roads. A limited amount of livestock grazing occurred seasonally. Mule deer and elk were present on this study area as well; however deer were not hunted, whereas elk were subject to intensive management through annual harvests and active translocation projects. The study site was part of the Oquirrh-Stansbury Cougar Management Unit 18, but both of these properties were closed to the public and cougar hunting was prohibited. Human density adjoining the study area varied from 232/100 km² in rural Tooele County to 47,259/100 km² in urban Salt Lake County (United States Census Bureau).

Methods

We monitored cougar populations within the 2 study areas simultaneously from early 1997 to December 2004. We estimated demographic parameters for each population based on radiotelemetry data collected between 1996 and 2004 on Monroe and from 1997 and 2004 on the Oquirrh. We calculated estimates of life-history parameters for cougars on the Oquirrh site during 1997 and 1998 from raw data presented in Leidolf and Wolfe (Utah State University, unpublished data). We performed statistical comparisons with the use of SAS (V.8) software. We report all descriptive statistics as mean \pm SE unless otherwise noted.

Radiotelemetry and Harvest

We conducted intensive capture efforts during winter (Nov–Apr) each year of the study. We captured cougars by pursuing them into trees, culverts, cliffs, or mine shafts with trained hounds (Hemker et al. 1984). We immobilized each animal with a 5:1 combination of ketamine HCl and xylazine HCl (Kreeger 1996) at a dose of 10 mg ketamine plus 2 mg xylazine/kg of body weight. We administered immobilizing drugs with a Palmer CO₂ pistol (Powder Springs, Georgia), jab stick, or hand-held syringe. We collected tooth (vestigial premolar, P2) samples for age determination by counts of cementum annulations. We sexed, aged, weighed, measured, tattooed with a unique identifier, and equipped with a radiocollar (Advanced Telemetry Solutions, Isanti, Minnesota) and a microchip (AVID Co., Norco, California) every adult animal captured. We checked adult females for evidence of lactation during handling. We tattooed, microchipped, and released all kittens too small to wear a radiocollar. We conducted all procedures in accordance with Utah State University Institutional Animal Care and Use Committee standards (Approval No. 937-R).

We relocated all radio-collared cougars with the use of aerial and ground-based telemetry techniques (Mech 1983). We conducted telemetry flights bimonthly on both sites as weather conditions permitted. We also relocated cougars

opportunistically with ground-based telemetry by plotting radiotriangulated locations on United States Geological Survey 7.5' topographic quads with the use of Universal Transverse Mercator coordinates (zone 12, North American Datum 1927). We stored all locations in a Geographic Information Systems (GIS) database (ArcView, ESRI Products, Redlands, California).

Over the course of the study, radiocollared cougars on Monroe Mountain were not protected from harvest beyond normal legal stipulations outlined in the UDWR hunting proclamations. Annual hunter-kill was regulated by apportionment of a limited number of hunter permits, issued by the UDWR on the decision of the State Wildlife Board. The Camp Williams and Kennecott properties were closed to hunting throughout the study; however, radiocollared cougars leaving those properties were considered legal take on adjacent private and public lands within Unit 18 during the 1997–2001 hunting seasons. Radiocollared cougars on that unit were protected after 2002.

Demographic Parameters

Density.—We measured cougar density as the total number of adult and subadult cougars/100 km² present during winter. Our a priori goal was to capture and collar as many individuals as possible. In this sense, we attempted to conduct a census of the population during winter, but during no year were we able to capture all independent cougars. To derive a conservative estimate of the number of unmarked animals on the site, we used 2 methods. First, because males and females can generally be differentiated by track size (Fjelline and Mansfield 1989), we considered multiple track sets of same-sexed animals encountered in the same watershed one individual. Given the large ranges of cougars, we felt that the primary watersheds on the site ($n = 4$; mean \pm SD = 361 ± 95 km², range = 237–462 km²) provided a practical threshold for differentiating individuals, as these basins approximated the size of a male home range. This does not negate the possibility that some individuals were double-counted; however, the effect of this error on the population estimate was small due to the number of animals that fell into this category annually. Second, we backcalculated birthdates of radiocollared cougars from age estimations based on tooth wear and counts of cementum annulations and used this information to assess our estimates of uncollared individuals from track evidence and hunter harvest. We excluded males backdated in this manner from the population estimate when they were <3 years old because of the likelihood that they were recent immigrants. Because females tend to be philopatric (Sweaner et al. 2000), we included them in the population estimate as resident subadults at the backcalculated age of 1–2 years. Although there are exceptions to these arbitrary dispersal rules, they provide a reasonable cutoff point for population estimates based on known cougar behavior (Beier 1995, Sweaner et al. 2000). We summed the total number of animals detected (from all means: capture, deaths, tracks) in June at the end of the capture and hunting seasons. This number most accurately represented the

population during the period June to December of the preceding year (Choate et al. 2006).

Road densities were high across both study areas. In addition to using 4-wheel-drive vehicles, we conducted winter tracking efforts on horseback and snowmachine in order to reduce bias associated with different levels of access. Using multiple methods also helped to reduce bias in terms of the social classes most vulnerable to detection due to frequent road crossings or small home ranges (Barnhurst 1986). Snow conditions influenced our ability to detect tracks, and therefore dry winters may have some bias associated with population counts; however, this bias was likely consistent between sites, as both study areas are subject to similar weather patterns.

We based study-area boundaries on major roads surrounding the site; therefore we used ecologically relevant vegetative and topographic features to delineate and quantify habitat within the study-site perimeter. We used the criteria of Laing and Lindzey (1991), which excluded valley bottoms and landcover types dominated by urban and agricultural uses. Maps represent geographical area on the planar surface and do not account for slope differences in mountainous terrain where actual surface area is greater. This discrepancy in area calculation leads to an increasing overestimation of population density as the ruggedness of the terrain increases. In order to increase the accuracy of the density estimates we used GIS software (ArcView surface to area ratio extension, Jenness Enterprises, Flagstaff, Arizona) to calculate the surface areas of habitat within study-site perimeters.

Age structure.—We determined age at the time of capture by visual inspection of tooth wear and gumline recession (Ashman et al. 1983, Laundré et al. 2000). In a few cases we used counts of cementum annulations (Matson's Lab, Milltown, Montana). To test for age differences among treatment groups (site and sex combinations), we used a 2-way factorial analysis of variance in a completely randomized design with unequal variances. We adjusted significance levels for pairwise mean comparisons to control experimentwise Type I error with the Tukey-Kramer method.

Cause-specific mortality.—We determined causes of mortality through visual inspection and necropsy of carcasses. When we could not determine cause of death in the field, we submitted the carcass to the Utah State University Veterinary Diagnostics Lab for detailed analysis. We calculated mortality by tallying cause of death among radiocollared animals and unmarked animals found opportunistically during tracking sequences. We pooled all human-related causes by site and tested for proportional differences with the use of chi-square (χ^2) tests.

Survival.—We calculated survival annually for all radiocollared adult and subadult animals from each population. To account for staggered entry and censoring due to the additions and losses of radiocollared animals to the sample, we used a Kaplan-Meier product limit estimator (Kaplan and Meier 1958). We estimated annual survival by defining

the start of sample intervals as 1 December of each year. By beginning the sampling interval prior to the beginning of the hunting season (15 Dec), we ensured that human-related mortality is accounted for only once during a single nonoverlapping period in each year. We calculated measures of precision for the computed survival rates from procedures described by Cox and Oakes (1984; cited in Pollock et al. 1989). We compared survival curves between sites with the use of the log-rank test (Pollock et al. 1989).

Fecundity.—We measured fecundity as the proportion of sexually mature females detected with litters-of-the-year (kittens <1 yr) on site during winter. We counted litters during snow tracking and capture efforts. We checked all females taken in the hunt for signs of lactation, which helped account for otherwise undocumented reproduction. Kittens >3 months old are only found with their mothers 20–43% of the time (Barnhurst 1986), but we tracked many female cougars on multiple occasions, thereby increasing the probability of detecting kittens, if present. We did not attempt any analyses on the actual number of kittens born per litter, because of the difficulty in determining the actual number of kittens when ≥ 2 track sets were found. There are 2 potential sources of error in this estimate. First, it is possible that some maternal females experienced whole-litter loss prior to the winter tracking season, and therefore a proportion of nonlactating females or those without kittens may actually have been reproductively active that season. Second, kittens <2 months old are not mobile, and so this cohort would also have been missed through track-based counts. Consequently, both the number of kittens per litter and the proportion of reproductively active females are biased low. The minimum percentage of females caring for young provided an annual estimate of productivity for each population (Barnhurst 1986). We used paired *t*-tests to detect differences in mean fecundity rates pooled over the entire study interval.

Dispersal.—We tattooed the ears of all kittens handled on the Oquirrh mountain site in the event that they were recaptured as adults. For the Oquirrh Mountain animals, we were able to calculate several crude estimates of dispersal distance and direction opportunistically based on harvest returns of animals marked as kittens. In addition, we monitored subadults captured as transients on Monroe via radiotelemetry for extrasite movements, thus providing some information on coarse-scale movement patterns. We calculated distances as a straight line between capture site and death site or the center of the home range.

Landscape Configuration

We used measures of landscape configuration to assess the overall degree of connectivity of the study sites to surrounding habitats within their respective ecoregions. Connectivity is defined here as “the degree to which the landscape facilitates or impedes [animal] movement among resource patches” (Taylor et al. 1993). We used descriptions provided by Laing and Lindzey (1991) to delineate potential connective habitats between the study areas and neighboring patches. In assessing connectivity for cougars we used only

easily quantifiable landscape variables and did not consider potential psychological barriers, although there is some evidence that outdoor lighting may function as such (Beier 1995). We derived the following metrics: size (km²), shape (perimeter–area ratios), greatest interpatch distance, percent of perimeter connected to neighboring habitat patches, width of connective habitat, and percent of perimeter impermeable to cougar movement. Impermeability refers to landscape features that prohibited, filtered, or redirected animal movement (Ernest et al. 2003, Forman et al. 2003), such as the Great Salt Lake, interstate highways, and urban areas. Some of these features may not form absolute barriers, but they can act as an impediment to animal movement. Perimeter–area ratios are a unitless metric that provided a relative measure of how circular (or how much edge) one study area had relative to the other. We derived these measures in ArcView using the spatial analyst extension and a 30-m digital elevation model of the state of Utah.

Results

Radiotelemetry and Harvest

Capture.—We captured and marked 110 individual cougars on the 2 study sites, representing 145 capture events (Table 1). In addition, we found one dead cougar opportunistically during tracking on the Oquirrh site. We conducted captures on Monroe Mountain from January 1996 to March 2004 and on the Oquirrh site from February 1997 to March 2004. Rugged terrain and frequent animal use of culverts, mine shafts, and lava tubes hindered the collection of ground-based telemetry observations. Consequently most telemetry data were derived from aerial surveys. Monitoring times for Monroe cougars averaged 758 days (range = 2–3140 days) for females, and 194 days (range = 3–662 days) for males. On the Oquirrh site we monitored females for a mean of 810 days (range = 14–2674 days) and males for 399 days (range = 76–1173 days). Differences between sexes reflected the smaller sample of males, their greater tendency to emigrate, and shorter residence times.

Monroe Mountain cougar harvest.—For the period 1990–1995, prior to initiation of this study, a mean of 15.6 (range = 14–19) hunting permits were issued annually, corresponding to a mean kill of 8.7 cougars per year (range = 6–12), and a mean hunter success of 54.0% (range = 40.7–64.9%). In 1996, the number of permits issued increased 33.7% over the 1990–1995 mean. In 1997, the number of permits increased 40% over 1996 levels and 151% over the 1990–1995 mean. Between 1999 and 2000, the number of permits issued decreased to 1990–1995 mean levels and was again decreased for the 2001 season. During the years of heavy harvest (1996–2001), mean per-capita hunting pressure (i.e., the proportion of the population that was legally harvestable) was 87% (range = 68.5–100%). During the years of reduced harvest (2002–2004) mean per-capita hunting pressure was 25.7% (range = 22.7–29.4%; Table 2). During the study 164 permits were issued, 79 cougars were killed (51 M, 28 F), and total hunter success was 48.1%, whereas mean annual hunter success was 46.5%

(1996–2001) and 73.3% (2002–2004; Hill and Bunnell 2005). The general decline in the number of hunting tags issued over time was partially in response to preliminary study results.

Oquirrh Mountain cougar harvest.—From 1996 to 2001 radiocollared animals on Unit 18 were considered legally harvestable. Cougars on the Camp Williams and Kennecott properties were protected, but these areas were surrounded by private and public lands open to hunting, making any study animal found offsite legal quarry. Beginning in 2002, all radiocollared animals on the unit were protected by law regardless of property ownership to facilitate a concurrent study. During our study 5 radiocollared cougars were killed just outside the study site boundaries (4 M, 1 F). Of these, the 4 males were legally harvested, whereas the female was taken after the 2002 moratorium on radiocollared study animals.

Demographic Parameters

Density.—Estimated high densities (cougars/100 km²) were similar between sites (Oquirrh, 2.9; Monroe, 3.2); however, trends in this parameter differed markedly (Fig. 2). Density on Monroe showed a consistent decline during the years of heavy harvest (1997–2001), which leveled off when permits were reduced by 80%, averaging 2.0 ± 0.3 (2002–2004). Oquirrh density showed minimal variation over the study interval averaging 2.8 ± 0.1 (Fig. 2).

Age structure.—Age estimates determined upon initial capture were pooled by sex and site for the entire study period (Table 1). Sexually mature cougars from the Monroe population ($n = 57$) averaged 3.4 ± 0.2 years ($F = 3.7 \pm 0.4$; $M = 3.1 \pm 0.3$). Adult cougars from the Oquirrh population ($n = 33$) averaged 4.6 ± 0.3 years ($F = 5.9 \pm 0.5$; $M = 3.4 \pm 0.4$; Fig. 3). Mean cougar ages differed both by study site (Monroe cougars < Oquirrh cougars; $F = 9.0$, $df = 1, 60.3$, $P = 0.004$) and by sex ($F > M$; $F = 13.8$; $df = 1, 60.3$; $P < 0.001$). Further, we found evidence of an interaction between sex and site ($F = 5.31$; $df = 1, 60.3$; $P = 0.025$). Within the Monroe population male and female mean ages did not differ ($t = 1.21$; $df = 54.6$; $P = 0.625$), whereas Oquirrh females were significantly older than their male counterparts ($t = 3.70$; $df = 30.2$; $P = 0.003$). Between sites, Oquirrh females were older than Monroe females ($t =$

–3.53; $df = 38.8$; $P = 0.004$), but male ages did not differ between sites ($t = -0.54$; $df = 22.5$; $P = 0.949$).

Cause-specific mortality.—Mortality on the Monroe site was predominantly human caused (74%), with legal harvest accounting for 81% of human-caused ($n = 26$) and 60% of total mortality ($n = 35$) (Fig. 4). Causes of mortality on the Oquirrh site varied (Fig. 4). All human causes (including roadkill) comprised 53% of the total mortality ($n = 17$) and of this, legal harvest accounted for 44% of all human-caused mortality ($n = 9$) but only 24% of the total. Levels of human-caused mortality differed between sites ($\chi^2 = 7.5$; $P = 0.006$). Various forms of poaching (neck snares, illegal hunter-kill) occurred sporadically on both sites (Monroe, $n = 2$; Oquirrh, $n = 1$), though alone, this did not represent a significant source of mortality for radio-collared animals.

The second leading cause of death on both sites was intraspecific predation, comprising 17% ($n = 6$) and 18% ($n = 3$) of total mortality on the Monroe and Oquirrh sites, respectively. During the years of high per-capita harvest pressure on Monroe, all victims of intraspecific aggression were resident adult females ($n = 4$), whereas during the period of light harvest all victims were subadult males ($n = 2$). On the Oquirrh, 1 victim was a dispersal subadult male and 2 were adult females. Notably, one of these

instances was an adult female cannibalizing another female with dependent young. Two years later, the survivor in this encounter was killed by an unidentified cougar. Cause of death could not be determined in three cases (2 F, 1 M), but did not appear to be human-related.

In addition to direct mortality, ≥ 11 kittens from 5 different litters on Monroe were orphaned when their mothers were killed during the winter hunt ($n = 10$) or during summer depredation control actions ($n = 1$). We confirmed the death of one orphaned litter (2 kittens, approx. 6 months old) due to dehydration and malnutrition. On the Oquirrh, one male kitten was orphaned at the estimated age of 9 months when its mother was killed by an automobile. This animal survived 6 weeks before being taken in a depredation control action on a small ranch just outside of Salt Lake City. A litter of 3 4-month-old kittens died following the disease-related death of their mother. One other male kitten was marked at the age of 7 months following the poaching-related death of its mother in January 2002. It survived at least 2 months before radio contact was lost. Aside from this individual, no other orphans were detected following the deaths of their mothers or as adults on either study area in subsequent years.

Survival.—Adult survival varied between sites and among years (Fig. 5). On Monroe, survival tracked harvest

intensity, ranging from a high of 1.0 in 1996, just prior to the initiation of the treatment period, and declining to a low of 0.36 ± 0.33 (95% CI) in 2001, the end of high per-capita hunting pressure. Survival on the Oquirrh showed moderate variation, ranging from 0.63 ± 0.28 to 0.91 ± 0.17 . Trends in survival mirrored those of density on both sites, averaging 0.64 ± 0.07 (\pm SE) on Monroe and 0.76 ± 0.04 on the Oquirrh. Analysis of trends over the entire interval suggested a difference in survival between sites ($\chi^2 = 3.41$; $df = 1$, $P = 0.068$).

Fecundity.—Reproduction varied between sites and years (Fig. 6). The number of litters detected annually ranged from 0–9 on Monroe and from 1–5 on the Oquirrh, averaging 0.24 ± 0.04 (Monroe) and 0.34 ± 0.05 (Oquirrh) litters per sexually mature female. Although rates did not differ statistically between sites ($t = -1.23$; $df = 7$; $P = 0.258$), fecundity on Monroe tracked the population decline and included a zero detection rate in 2002, the year following the lowest population estimate. At that time there were ≥ 5 sexually mature females present. The lowest fecundity estimate for the Oquirrh population was recorded the year after a 50% reduction in elk numbers. These animals were removed for reintroductions in other states.

Figure 5. Estimated annual survival rates for radiocollared cougars, Monroe and Oquirrh Mountain study sites, Utah, USA, 1996–2004.

The removal was conducted over 2 years and was comprised primarily of cows and calves, the sex and age classes most vulnerable to cougar predation (Murphy 1998). The number of resident females on the Oquirrh site was smaller ($\bar{x} = 9.6/\text{yr}$) than on Monroe ($\bar{x} = 15.7/\text{yr}$), which may have influenced the variability in fecundity. Litter sizes averaged 1.7 and 1.9 kittens per litter on Monroe and the Oquirrh, respectively. Based exclusively on the Oquirrh site using only kittens handled and marked (4–10 months post partum), the sex ratio was even (9 F, 9 M).

Dispersal.—Several animals were captured and marked either just prior to, or during dispersal. Four cougars (1 F, 3 M) moved from Monroe to neighboring mountain ranges 19–55 km distant. Two of these (1 F, 1 M) established residency in habitat adjacent to the study area; one was recaptured and his collar removed (fate unknown); and one was harvested 42 km northeast on the Fishlake Plateau (Fig. 7).

Seven dispersals were documented on the Oquirrh site (2 F, 5 M), ranging in distance from 13 to 85 km (Fig. 7). Of these, 3 (1 F, 2 M) settled elsewhere in the Oquirrh Mountains; 1 female moved to the Simpson-Sheeprock Mountains; 2 males moved to the Stansbury Mountains where they were hunter-killed as transients; and 1 male dispersed to the Mt. Timpanogos region of the southern

Wasatch Mountains, crossing a 6-lane interstate and ≥ 5 km of city streets to get there.

Landscape Configuration

The study sites exhibited similar perimeter-area indices, but notable differences in connectivity and perimeter permeability (Table 3). During the study, no substantial movement barriers existed along the perimeter of Monroe Mountain, and in general, the unit was well connected to other habitats of similar quality within the Southern Mountains ecoregion (Fig. 7).

In contrast, only 5% of the Oquirrhes' perimeter was connected to neighboring habitat and approximately 40% was nearly impermeable to cougar movement. Movement barriers included the southern shore of the Great Salt Lake (7 km), the Salt Lake metro area (50 km), and a heavily traveled segment of Interstate 15 (2 km), which bisected the Traverse Mountains (Fig. 7). The remaining 55% graded into salt desert scrub communities offering little vegetative cover or surface water (West 1983). Additionally, residential development emanating from the Salt Lake–Provo metropolitan corridor was much greater around the Oquirrh site.

Overall, the Oquirrhes exhibited much thinner and more tenuous connectivity to neighboring patches of generally poorer quality (i.e., lower primary production), a pattern typical of basin and range topography (Fig. 1). This topographic fragmentation combined with anthropogenic fragmentation in the foothills and valleys around the site rendered this area susceptible to isolation (see Beier 1995).

Discussion

Influence of Harvest on Cougar Populations

Demographic differences between study populations reflected the prevailing management strategies. Cougar removal on Monroe Mountain ranged from 17.6–54.5% of the adult population exceeding 40% for 4 of the 5 years of high per-capita hunting pressure. Females comprised 32% of the harvest but 100% of depredation control and poaching mortality. Under this regime the population declined by $>60\%$, whereas the Oquirrh Mountain population remained stationary. Moreover, the Oquirrh population had a significantly higher mean age among females and a smaller proportion of subadults. Age structure of males did not differ between sites, suggesting either: 1) males and females had a fundamentally different age distribution in the general population, or 2) the unhunted portion of the Oquirrhes was too small to adequately protect males. Density, survival, and fecundity were all negatively associated with sustained high per-capita hunting pressure on Monroe Mountain, whereas, with the exception of fecundity, these measures remained relatively constant over the same interval on the Oquirrh site. Though humans represented the single greatest source of mortality for animals traveling outside the Oquirrh study site, the absence of harvest within the study area suggests that the Camp Williams–Kennecott properties collectively acted as a functional refuge. Resident females were the primary beneficiaries of this protection. On the Monroe site, the prevalence

Table 3. Measures of landscape connectivity, Monroe and Oquirrh Mountain study sites, Utah, USA, 1996–2004.

Landscape metrics	Monroe	Oquirrh
Perimeter (km)	178	150
Area (km ²)	1300	950
Perimeter:area	0.137	0.157
Greatest interpatch distance (km)	7	25
Perimeter impermeable (%)	0	40
Perimeter connected (%)	33	5
Width connective habitat (km)	7–21	2–4.5

of human-caused mortality, lack of starvation as a mortality cause, and moderately stable prey populations (UDWR, unpublished data) suggest that this level of mortality was largely additive. Annual harvests exceeding 30% of the adult population consisting of 42% females, carried out continuously for >3 years, can reduce density, fecundity, and skew age structure.

The consequences of sustained exploitation may not be limited to numeric population changes. Fecundity rates on Monroe tracked per-capita harvest pressure with a 1-year lag. We did not observe compensatory reproduction under increased harvest levels, as has been noted for some monogamous carnivores (Knowlton 1972, Frank and Woodroffe 2001). Smuts (1978), Knick (1990), and Wielgus and Bunnell (2000) reported analogous findings for hunted populations of African lions (*Panthera leo*), bobcats (*Lynx rufus*), and brown bears (*Ursus arctos*), respectively. One hypothesized function of male territoriality among polygynous carnivores is to increase offspring survival by excluding nonsire males from the natal range (Bertram 1975, Ross and Jalkotzy 1992), thereby reducing infanticide and optimizing fitness (Packer and Pusey 1984, Swenson 2003). Cougars are known to exhibit this behavior (Hornocker 1970, Hemker et al. 1986, Pierce et al. 1998) suggesting that hunted populations may experience increased levels of infanticide (Swenson 2003). On Monroe heavy harvest and subsequent social instability may have reduced the reproductive capacity of the population and therefore its ability to compensate losses.

Factors Influencing the Rate of Population Recovery

From 2002 to 2004 per capita hunting pressure on Monroe Mountain was reduced to <30%, during which survival and fecundity increased. Nevertheless, following 3 seasons of light harvest the population had only recovered to 52.4% of its 1997 levels, with nearly equal sex ratios and reproduction lagging behind resident replacement.

Lindzey et al. (1992) in Utah and Logan and Sweanor (2001) in New Mexico conducted controlled removals to examine the demographic mechanisms and time scales of population recovery. These authors noted that female recruitment was achieved via philopatric behavior or diffuse dispersal, whereas male recruitment was solely the product of immigration. Further, they suggested that recovery from 27–58% population reductions could be attained within 2–3 years under complete protection. However, those removals

spanned only a single season and large sanctuaries (>1,000 km²) buffered the treatment areas. In contrast, the Monroe population had only a 7-month annual reprieve from hunting pressure and was surrounded by units subjected to similar levels of exploitation.

The degree of landscape connectivity can mediate demographic connectivity, and is thus an important factor in population recovery or persistence (Beier 1993). Strong connectivity is the most likely reason we detected transients on Monroe each winter. These animals buffered population declines (Brown and Kodric-Brown 1977) but may have contributed to social instability. It has been hypothesized that the removal of resident males may induce a “vacuum effect” in which multiple transients vie for a vacant home range, potentially leading to an increase in population density (Shaw 1981, Logan et al. 1986). Our results lend only limited support to this argument. We observed an increase in the relative proportion of subadult males subsequent to removal of resident males, whereas the overall population declined. In general, males tend to disperse farther than females, remain transient longer, and are less tolerant of other males (Cunningham et al. 2001, Logan and Sweanor 2001, Machr et al. 2002). Conversely, females often exhibit philopatric behavior, reproduce at an earlier age than males, and tolerate spatial overlap with other females (Murphy 1998, Pierce et al. 2000). Therefore, the transient segment of the cougar population is likely to be male biased (Hansson 1991). Removal of resident males provides territory vacancies that may be contested by multiple immigrants, thereby temporarily increasing the proportion of males in the population but not the overall density of males in the general population. Based on preliminary data from the post-treatment period, we hypothesize that following sustained disturbance, population recovery will proceed in 2 general phases: numerical and functional. Functional recovery implies not simply increases in absolute density but rather stabilization of social relationships and decreases in the variability of vital life-history rates. Female-biased sex ratios, low male turnover rates, and higher per-capita productivity may be used as relative indices of functional recovery.

Harvest Dynamics and the Regional Metapopulation

The metapopulation concept has been proposed as a framework for large-scale management of cougars (Beier 1996, Sweanor et al. 2000, Laundré and Clark 2003). In the strictest sense, a metapopulation is the composite of numerous spatially discrete subpopulations exhibiting independent behavior over time. The dynamics of the metapopulation are the net result of the shifting balance between local extinctions and recolonizations facilitated by intermittent dispersal events. The latter quality defines the classic metapopulation (Levins 1969, Hanski and Simberloff 1997).

The source–sink model provides a mechanism for metapopulation dynamics by emphasizing recruitment patterns within and among populations. The more general

definition describes a sink as a net importer and a source as a net exporter of individuals over time (Pulliam 1988). Demographically, the Monroe and Oquirrh populations approximate the sink–source archetypes, respectively, albeit as a result of exploitation levels rather than habitat quality (e.g., Novaro et al. 2000). When harvest and its apparent impacts are considered, the Monroe population exhibited sink-like mortality. Notwithstanding low kitten production, each winter new animals, primarily subadult males, were captured on the site. Some of these individuals may have been resident progeny but mammalian dispersal patterns tend to be male-biased (Greenwood 1980). Low productivity and high immigration rates are the essence of a sink population.

In contrast, the Oquirrh population exhibited static density and emigration of resident progeny. No marked female kittens were detected as adults on the site. Indeed, 5 tattooed kittens (2 F, 3 M) were later killed elsewhere in the Oquirrh or on neighboring mountain ranges up to 85 km distant. Solely based on age (4 yr) the female emigrants could have raised one litter to independence, whereas the males were killed immediately upon leaving their natal ranges, thereby subsidizing the harvest in adjacent units. On the Oquirrh site female dispersal appeared to be related to the saturation of available habitat, suggesting a source-like population structure.

When the prevailing harvest rate is considered a component of habitat quality, then a spatially clumped harvest distribution can promote source–sink dynamics. This may result in an immigration gradient directed toward patches such as Monroe Mountain, where strong connectivity coupled with low population density create an ecological trap (i.e., a productive habitat that displays sink-like mortality patterns, e.g., Bailey et al. 1986, Kokko and Sutherland 2001). These sites represent examples of populations exhibiting different dynamics simultaneously within a metapopulation. Importantly, source–sink characteristics may be dynamic and interchangeable depending on how prevailing management interacts with habitat productivity and connectivity. For example, the Monroe population illustrates the potential consequences of overharvest, yet is situated within a large semicontiguous tract of habitat spanning the state with extensions into Colorado, Idaho, and Arizona. Conversely, the Oquirrh population appears demographically stable, but lies within an ecoregion defined by weak connectivity among sparsely distributed desert ranges. Under different objectives, conservative management could render the Monroe population a source, whereas the

Oquirrh population should be managed under the small population paradigm (Caughley 1994).

Management Implications

At the scale of the local population or management unit, annual harvests exceeding 40% of the nonjuvenile population for ≥ 4 years can not only reduce density but may also promote or maintain a demographic structure that is younger, less productive, and socially unstable. At an ecoregional scale the difficulties of reliably delineating discrete populations (Pierce and Bleich 2003) and their respective sizes (Choate et al. 2006) emphasize the importance of managing cougars in a metapopulation context. That said, source–sink characteristics may be more amenable to field evaluation than the extinction and recolonization events that define classic metapopulations. Numeric recovery of overexploited populations may initially depend more on immigration than in situ reproduction. Under moderate to heavy exploitation this task may require: 1) an assessment of habitat connectivity between identified sources and sinks, and 2) the presence of truly functional source populations, most readily managed through the establishment of refugia.

Acknowledgments

ABSTRACT Harvest indices are used by state wildlife management agencies to monitor population trends and set harvest quotas for furbearer species. Although harvest indices may be readily collected from hunters, the reliability of harvest indices for monitoring demography and abundance of the harvested species is rarely examined, particularly amongst large carnivores. The overall objective of this study was to assess whether cougar (*Puma concolor*) harvest statistics collected by wildlife managers were correlated with changes in cougar demography, mainly survival rates and abundance. We estimated key demographic parameters for 2 cougar populations in Utah over 17 years during which we monitored 235 radio-collared cougars. We then compared these demographic parameters to harvest statistics provided by the Utah Division of Wildlife Resources over the same time period for the Oquirrh-Stansbury (lightly harvested population) and Monroe (heavily harvested population) harvest management units. In the Oquirrh-Stansbury unit, the percent of harvested cougars >6 years old was positively correlated with annual survival, indicative of a population experiencing several years of high survival resulting in an older age structure. Percent of permits filled and cougar abundance were also significantly correlated, suggesting higher hunting success with increased density. In the Monroe management unit, the annual percent of permits filled was correlated with changes in overall annual survival and male and female annual survival. Of utmost importance, pursuit success (cougars treed/day) increased with the number of cougars on the unit suggesting that pursuit indices may be an informative metric for wildlife managers to determine cougar population trends. Because both management units were subjected to contrasting mortality regimes, results provided by this assessment could potentially be applied to additional management areas sharing similar ecological characteristics and harvest metrics. Published 2015. This article is a U.S. Government work and is in the public domain in the USA.

KEY WORDS abundance, competing risks, exploitation, harvest statistics, management, mortality, *Puma concolor*, survival.

Knowledge of the status of a carnivore population is essential for the development and implementation of an effective management plan (Ginsberg 2001, Pollock et al. 2012). Carnivores are often managed through regulated sport hunting to maintain viable populations (Sillero-Zubiri and Laurenson 2001, Keefover-Ring 2005), and reduce impacts of predation on their principal prey species and domestic livestock (Treves and Karanth 2003, Anderson et al. 2010, Loveridge et al. 2010). Management agencies often face the difficulty of opposing demands for more effective carnivore control to protect human safety, big game populations, and domestic livestock, and the demand for

additional carnivore-hunting opportunities by sportsmen and outfitters and even societal demands for protection from exploitation (Sillero-Zubiri and Laurenson 2001, Anderson et al. 2010, Funston et al. 2013).

Given their large spatial requirements, low densities, and elusiveness, the management of large carnivores is often challenging because of the difficulties in estimating vital rates and population abundance (Gese 2001, Pollock et al. 2012). Cougar (*Puma concolor*) management nevertheless depends on the ability to monitor demographic responses to changing policies and management actions (Anderson et al. 2010). Unfortunately, state and provincial wildlife agencies are often required to make management decisions without the demographic information needed to monitor and maintain sustainable cougar population levels from one harvest season to the next (i.e., adaptive harvest management) because this information is often unavailable. Frequently, harvest

Received: 1 December 2014; Accepted: 13 August 2015

¹E-mail: lise.aubry@usu.edu

composition statistics (e.g., age structure and sex composition) are used in lieu of measured demographic variables of population performance and abundance (Whittaker and Wolfe 2011). Harvest data alone is not sufficient for estimation of population size but rather should be used in conjunction with additional demographic data such as annual survival rates (Erickson 1982, Kolenosky and Strathearn 1987, Lindzey 1987, Rolley 1987, Chilelli et al. 1996). The question arises as to whether harvest statistics and harvest composition are reasonable approximations of changes in demographic performance (e.g., survival) and population abundance over time.

Of all demographic estimates, wildlife managers are most interested in monitoring animal abundance because annual changes in abundance measure the net balance among births, immigrants, deaths, and emigrants (BIDE), and indicate whether there is a surplus that can be sustainably harvested from year to year. Because a complete census is never possible, abundance must be estimated using appropriate methods that can account for imperfect detection and even multiple counting of individuals. Indeed, a number of approaches have been proposed for estimating cougar abundance and associated densities (Van Dyke et al. 1986, Smallwood and Fitzhugh 1995, Choate et al. 2006), but all have logistic limitations and statistical assumptions that are difficult to meet in a field setting.

When abundance becomes too difficult to accurately estimate, attention is sometimes transferred to the BIDE vital rates that determine abundance to monitor population trends rather than abundance per se. Immigration and emigration may play a large role in the change of male cougar abundance (Robinson et al. 2008), but in the female-limiting component of the population attention should be focused on reproductive success and survival (Lambert et al. 2006). Regardless of whether the focus is on the male or female component, cause-specific mortality analyses can provide deeper insight into the factors underlying management-relevant changes in survival and population dynamics (e.g., hunting vs. vehicle collisions).

The Utah Division of Wildlife Resources (UDWR) currently uses harvest rate, percent females in the harvest, and number of cougars treed per day to set the following years harvest quotas (Utah Cougar Advisory Group 2011). The cougars treed per day can be thought of a catch-per-unit-effort estimator (Choate et al. 2006). Although there was no significant relationship between cougars treed/day and the size of 2 cougar populations monitored for 6 years (Choate et al. 2006), the UDWR incorporates this index in their formula to determine harvest levels. We calculated estimates of key demographic parameters from 2 cougar populations that were intensively monitored in Utah for 17 years, and compared these estimates to harvest statistics provided by the UDWR over the length of the study period. Cougars in the Oquirrh-Stansbury cougar management unit (OSCMU) were primarily exposed to non-hunting anthropogenic sources of mortality and cougars in the Monroe cougar management unit (MCMU) were mostly influenced by hunting mortality. Our objective was to assess the

correlations between currently used harvest statistics and independently derived population parameters within the OSCMU and MCMU.

STUDY AREA

We examined cougar populations on the OSCMU and MCMU, located in the Great Basin and Colorado Plateau ecoregions, respectively, in Utah. Mountain ranges in these ecoregions were surrounded by desert basins and formed a basin and range landscape. Annual precipitation ranged from 60 cm to 120 cm in the higher elevations to 15–20 cm in the desert basin regions with most of the precipitation arriving as snow in January and February (Moller and Gillies 2008). The Oquirrh-Traverse Mountains were dominated by Gambel oak (*Quercus gambelii*), sagebrush (*Artemisia* spp.), and Utah juniper (*Juniperus osteosperma*), whereas Monroe Mountain was dominated by pinyon (*Pinus edulis*)-juniper (*Juniperus* spp.) woodlands.

The OSCMU was located in north-central Utah on the eastern edge of the Great Basin (40.5°N, 112.2°W). The Oquirrh Mountains measured >950 km², but the study area was focused on a 500-km² area encompassing the northeastern slope on properties owned and managed by the Utah Army National Guard (Camp Williams) and the Kennecott Utah Copper Corporation. The site was bounded on the north by the Great Salt Lake and on the east by the Salt Lake Valley. Approximately, 55% of the study area was under the jurisdiction of the Bureau of Land Management (BLM), with the remainder held by individuals, grazing associations, mining companies, and the military. The study area was situated within the larger OSCMU, but both properties (Camp Williams and Kennecott) were closed to the public and cougar hunting was prohibited. Although radio-collared cougars leaving those properties were legally protected within the management unit, they were susceptible to poaching, depredation control, trapping, and road kill. Thus, this population was considered to be semi-protected.

Monroe Mountain comprised part of the Sevier Plateau in south-central Utah (38.5°N, 112°W). The study area measured approximately 1,300 km², and formed the central part of the Fishlake National Forest. Additional landholders included the BLM, the State, and various private interests. The study area was within the MCMU, where cougars were managed for sustainable hunting opportunities. Other carnivores present included bobcats (*Lynx rufus*) and coyotes (*Canis latrans*), which were both subject to trapping pressure. Resource use included livestock grazing (cattle, sheep), logging, fossil fuel exploration, and off highway vehicle recreation (e.g., all terrain vehicles). Stoner et al. (2006) provide a more detailed description of the study areas.

METHODS

Cougar Harvest in Utah

Nearly all cougars harvested in Utah are taken with the aid of dogs (Utah Cougar Advisory Group 2011). An individual hunter is restricted to holding either a limited entry permit or a harvest objective permit per season, and must wait 3 years to

reapply once they acquire a limited-entry permit. The bag limit is 1 cougar/season, and kittens and females accompanied by young are generally protected from harvest. Currently, the cougar hunting season runs from late November through late May on both limited entry and most harvest objective units. Some units are open year-round and some have earlier or later opening dates. Pursuit (chase or no-kill) seasons provide additional recreational opportunities over most of the state. The pursuit season generally follows the hunting season, but specific units have year-round pursuit and a few units are closed to pursuit (Utah Cougar Advisory Group 2011).

We used information covering 1996–2012 that was published in the most recent Utah Cougar Annual Report (Utah Division of Wildlife Resources 2012), which collated information for a number of harvest and pursuit statistics used by UDWR managers from the OSCMU and MCMU; reporting of each cougar harvested is legally mandated. We first focused on the 3 indices used to monitor cougar population trends and guide management in Utah: percent females in harvest, number of cougars treed per day, and number of cougars harvested annually. We examined additional harvest indicators that were specific to each sex (i.e., annual no. harvested males, % of males in the harvest) and harvest indicators that pertained to age (i.e., proportion of cougars that were ≥ 6 years of age in the harvest, the mean age of harvested animals each year). Finally, we examined statistics related directly to harvest regulations (i.e., % of hunting permits filled each year, no. sport-harvested cougars, no. harvest permits allotted, including all limited entry, conservation, and conventional permits; Utah Division of Wildlife Resources 2012).

Field Methods

From January 1996 to June 2012, we conducted capture efforts during winter (Dec to Apr). We pursued cougars with trained hounds, and then immobilized each cougar with a combination of ketamine hydrochloride (10 mg/kg) and xylazine hydrochloride (2 mg/kg; Fort Dodge Animal Health, Fort Dodge, IA) following recommendations in Kreeger (1996). We sexed, weighed, measured, ear tattooed, and microchipped (AVID, Norco, CA) each individual. For aging the animal, we extracted a vestigial premolar (P2) for aging with cementum annuli, a field estimate of age using gum-line recession (Laundré et al. 2000), and tooth wear (Ashman et al. 1983). We fitted all adult (>24 months) and sub-adult (12–24 months) cougars with a very high frequency (VHF) radio-collar (Advanced Telemetry Systems, Isanti, MN) or a global positioning system (GPS) collar (i.e., Televilt Simplex, Lindesberg, Sweden; LoTek 4400S, Newmarket, Ontario, Canada). We located cougars with a VHF collar twice a month with aerial or ground telemetry (Mech 1983); we attempted to acquire locations of cougars with a GPS collar every 3 hours. We marked kittens (0–12 months) that were too small to wear a radio-collar with a microchip (AVID) and tattooed their ears with a unique identification number. We released all animals at the capture site. For each population, data collection was based on

radio-telemetry information collected between 1 January 1996 and 30 June 2012. Animal capture and handling procedures were conducted in accordance with Utah State University Institutional Animal Care and Use Committee standards (approval no. 937-R).

The Utah cougar hunting season commenced in mid-November and continued to the end of May each year. However, most of the harvest occurred during a 4-month period when snow was on the ground (Dec to Mar). We used individual locations within the MCMU collected after 1 March 1996, directly after the harvest season, so we would not split a harvest season across an analysis year and to maximize use of available data (the first individuals were marked in Jan 1996); similarly, the study began in the OSCMU on the 1 March 1997.

The fate of most marked individuals was known with the exception of 11 cases for which we could not ascertain an emigration or death status. We ascertained emigration status and radio-collar failures for 35 and 47 individuals in the QSCMU and the MCMU, respectively (Table 1). Kittens that did not survive to age 1 were not included in the analyses because their fates were dependent on the fate of their mothers. However, kittens that survived to their first birthday and remained in the unit where they were initially marked were included in the analyses; through left-truncation, we included such individuals from age 1 onward in all analyses.

We determined the causes of mortality through visual inspection and necropsy of carcasses (Stoner et al. 2006). When we could not determine cause of death in the field, we submitted the carcass to the Utah Veterinary Diagnostics Lab (Logan, Utah) for a detailed necropsy. Precision of mortality dates varied: with GPS-collared and hunter-harvested animal mortality, dates were known to within 1 day, whereas we estimated dates for animals wearing conventional VHF radio-collars using the midpoint between the last live signal and the detection date of the first mortality signal (± 15 days).

Demographic Analyses

Classical survival models used in human demography (Kleinbaum and Klein 2005) are appropriate for estimating survival trajectories when individuals are followed from entrance into the study until death (Murray et al. 2010, Aubry et al. 2011, Sandercock et al. 2011). Various extensions to the non-parametric Kaplan–Meier (Kaplan and Meier 1958) estimator, such as the Cox Proportional Hazard model (CPH; Cox 1972), further allow identification of the measurable (i.e., observed) covariates associated with patterns in survival trajectories. We used semi-parametric CPH models because they do not require assumptions about the shape of the underlying mortality hazard (the force of mortality) over life. Rather, each covariate within the model is assumed to act multiplicatively (i.e., proportionally) on the baseline mortality hazard at each time step (Bradburn et al. 2003): $h_i(t) = h_0(t) \cdot \exp(\beta_i X_i)$ such as where h_0 refers to the baseline hazard (i.e., the hazard's value when all covariate values are null), X denotes a vector of

Table 1. Sex- and location-specific deaths by cause of mortality for radio-collared cougars in the Oquirrh-Stansbury Cougar Management Unit (OSCMU), 1997–2012, and in the Monroe Cougar Management Unit (MCMU), 1996–2012, Utah, USA.

covariates such as $X = (X_1, X_2, \dots, X_i)$, and t denotes time (in our case, time elapsed since marking; Murray and Patterson 2006). We conducted all analyses in R (version 2.15.0, Development Core Team 2012).

Standard survival estimators consider the elapsed time from some origin until the occurrence of death or failure. If ≥ 1 type of end point is of interest, these end points are called competing risks (Geskus 2011). With radio-telemetry data, a competing risk analysis can be used to attain unbiased estimates of cause-specific mortality, whereas standard tabular presentations of percentage representations for cause-of-death data are inherently biased (Heisey and Patterson 2006) but can nevertheless be useful to visualize the cause of death data. Because specific causes of mortality might be more reliable indicators of harvest statistics used to guide cougar management, we considered 2 dichotomies in mortality estimates. We estimated annual cause-specific mortality at each study area for human harvest versus all other causes of death, or all anthropogenic causes of mortality (i.e., harvest, poaching, depredation control, road kill, capture-related mortality) versus natural mortality agents (i.e., intra-specific strife, injury during predation attempt) using the R package *wild1* (Sargeant 2011, Wolfe et al. 2015). For the purpose of this assessment, we were specifically interested in estimating annual mortality from hunting exclusively (i.e., the harvest rate \hat{h}_t) because it should be most closely linked to harvest statistics if such relationships exist.

We used a minimum abundance index or population estimate for each management unit that included the number of adults and independent sub-adults (i.e., no longer with their mother) based on all captures, radio-telemetry, tracking, and mortality data (Logan and Swenor 2001, Choate et al. 2006, Cooley et al. 2009). We also calculated corresponding densities based on the size of each unit (adult and independent sub-adult cougars per 100 km²).

We used Spearman's rank correlation coefficient (r) to examine the relationships between the harvest indices collected by the UDWR and the independently derived demographic rates (Zar 1999). Correlation coefficients range from -1 (i.e., perfect negative correlation) to $+1$ (i.e., perfect

positive correlation), where a correlation of 0 indicates there is no relationship between the 2 variables. We used the standard error of a correlation coefficient to determine the confidence intervals around a true correlation of 0, and t -tests to test the null hypothesis that the true correlation was 0 (Zar 1999). For each analysis, we reported the correlation coefficient and associated P -value and considered correlation coefficients with P -values ≤ 0.10 significant.

RESULTS

Overall, demographic analyses were based on 235 marked individual cougars (MCMU: $n = 148$, 66 M and 82 F, 37 sub-adults and 111 adults; OSCMU: $n = 87$, 32 M and 55 F, 24 sub-adults and 63 adults). Seventeen individuals died of natural mortality and 89 of anthropogenic causes in MCMU. In the OSCMU, 28 individuals died of natural death versus 22 of anthropogenic causes (Table 1). In the MCMU, 72 individuals were harvested and 34 individuals died of non-harvest mortality (i.e., all other causes of death). Within the OSCMU, 16 individuals were harvested and 34 individuals died of other causes (Table 1). An additional 82 cougars were right-censored because they were still alive at the end of the study or because they emigrated from the management unit (47 in MCMU and 35 in OSCMU; i.e., the data they provided while on the study area was used until they emigrated out of the study area).

We calculated an abundance index akin to a minimum population abundance estimate for each unit (Fig. 1). In the OSCMU, this index fluctuated between 10 and 20 adults and independent subadult cougars over time, with a corresponding density that ranged from 2 to 4 adult and independent subadult cougars/100 km² (Fig. 1). In the MCMU, this index ranged from 10 to 40 adult and independent subadults, for a corresponding density of 1 to 3.5 adult and independent subadult cougars/100 km² (Fig. 1).

Unit-Specific Demographic Estimates and Harvest Statistics

Annual survival fluctuated over time in the OSCMU (Fig. 2A) and MCMU (Fig. 2B). Notably, in 1999 and 2012

Figure 1. Changes in A) cougar abundance and B) associated density index (cougars/100 km²), for adult and independent subadult cougars on the Oquirrh-Stansbury (1997–2012) and the Monroe (1996–2012) study areas, in Utah, USA.

annual survival in the MCMU was low (Fig. 2B). Male survival was consistently lower than female survival in both units, and survival was higher in the OSCMU compared to MCMU (Fig. 2).

In the OSCMU, the primary cause of death in males was harvest (Table 1, Fig. 3), and natural causes (injury, starvation) in females (Table 1). Intra-specific strife was also an important influence of overall mortality, equally distributed between females and males (Table 1). Individuals between ages 2 and 6 primarily died from harvest mortality or other sources of anthropogenic mortality (e.g., car collision, Wildlife Services removals). For individuals that died of non-harvest mortality, females died at a later age on average than males (Wolfe et al. 2015). Over the span of the MCMU, 67% of all individuals that died were harvested (Table 1, Fig. 3). All age-classes were subjected to harvest and non-harvest causes of mortality, and more individuals died between 2 and 4 years of age compared to any other age class.

Generally, in the OSCMU we observed a decrease in harvest indices over time. In the MCMU, however, we observed an increase in harvest indices over the last few years of the study. Specifically, increases were observed in the total harvest and in the percentage of harvest permits filled since 2006, along with an increase in the percentage of cougars harvested that were >6 years old and in the number of females harvested since 2009. The number of cougars treed/day (i.e., pursuit statistic) and mean age at harvest fluctuated over time with an increase in the pursuit statistic and harvest pressure since 2004 in the MCMU.

Correlation of Demographic Estimates and Harvest

We found significant correlations between several harvest statistics and demographic estimates for the OSCMU (Table 2) and MCMU (Table 3). In the OSCMU, we found the percent of permits filled and the minimum abundance index were positively correlated (Fig. 4A, Table 2). Further, the percent of individuals in the harvest

Figure 2. Changes in overall and sex-specific annual survival for radio-collared cougars in the A) Oquirrh-Stansbury and B) Monroe study areas in Utah, USA from 1997 to 2012 and 1996 to 2012, respectively.

Figure 3. Changes in annual harvest mortality estimates over time in the Oquirrh-Stansbury and Monroe study areas Utah, USA from 1997 to 2012 and 1996 to 2012, respectively.

>6 years old was positively correlated with annual survival, annual male survival, and annual female survival (Fig. 4B–D, Table 2). In the MCMU, which experienced greater hunting pressure, overall annual harvest mortality was principally influenced by male annual harvest mortality (Fig. 5A, Table 3). We also observed a negative relationship between the annual number of females in the harvest and annual survival (Fig. 5B, Table 3). Additionally, we found a negative correlation between the annual proportion of females in the harvest and annual survival (Fig. 5F, Table 3). Further, percentage of permits filled each year was positively correlated with overall annual survival, annual male survival, and annual female survival (Fig. 5, Table 3). We detected a positive relationship between the number of cougars treed/day and the annual abundance index (Fig. 5G, Table 3), suggesting that pursuit success increased with the number of cougars on the unit.

DISCUSSION

Monitoring survival and determining the abundance of large carnivores is a daunting task for many wildlife agencies. Being able to use indirect measures of abundance to monitor changes in population size and survival (i.e., harvest) has routinely been used for large carnivores and cougars in particular, for several decades (Beausoleil et al. 2008,

Whittaker and Wolfe 2011). However, knowing the relationships between these indirect measures or harvest indices and actual demographic parameters such as survival and population abundance requires long-term data collected with consistent field methodologies.

Even though intense harvest in the MCMU was a potential concern for sustainable management of cougars in this region, cougar densities assessed from the marked population indicated that densities rebounded and have been maintained at 3 adult cougars/100 km² over the last few years (Fig. 1). Immigration was a factor that we were not able to quantify, but the age structure indicated that an influx of cougars since 2006 has likely compensated for increased removal of cougar residents through hunting. Additional data on cougar movement in and out of the study area would be needed to quantify this influx, and the role immigration plays in maintaining stable dynamics (Sweaner et al. 2000, Robinson et al. 2008, Cooley et al. 2009). Abundance estimates obtained from the results of genetic mark-recapture procedures (Long et al. 2008, Kelly et al. 2012), and more sophisticated analytical methods such as dead recovery multi-state analysis (Koons et al. 2014) could help improve abundance estimates in the future. However, the question of whether a density of 3 adult cougars/100 km² is the target density that state wildlife agencies should manage for remains unresolved.

Densities ranged from 2 to 4 adult and independent subadult cougars/100 km² in the OSCMU and 1 to 3.5 adult and subadult cougars/100 km² in the MCMU (Fig. 1). According to the 2009–2021 Utah Cougar Management Plan (Utah Cougar Advisory Group 2011), high quality habitat was assigned a density range of 2.5–3.9 adult and subadult cougars/100 km², medium quality habitat was 1.7–2.5 adult and subadult cougars/100 km², and low quality habitat was 0.26–0.52 adult and subadult cougars/100 km². According to these standards, the OSCMU and MCMU cougar populations would be classed as high quality habitat. Because cougars have large home ranges, these numbers would be valid in locations where cougar home ranges are not constrained by human development and encroachment. This is not the case in the OSCMU, and might not hold true in the MCMU either.

Table 2. Correlations matrix between demographic parameters and harvest statistics in the Oquirrh-Stansbury Cougar Management Unit, 1997–2012, Utah, USA. Significant correlations ($P < 0.1$) are indicated with an asterisk.

Specifically, dispersing cougars are potentially exposed to car collisions and Wildlife Services removal. Also, demographic stochasticity alone could lead to small populations of cougars in both locations. We suggest that the UDWR consider re-examining their density and habitat quality indices for future cougar management, and the size of management units for a species whose populations are predominantly regulated by source-sink dynamics (Robinson et al. 2008, Cooley et al. 2009).

The most intuitive finding of our analysis was the positive correlation between the percentage of permits filled and the minimum abundance index in the OSCMU. This was a fairly simple relationship indicating that hunters were more successful when cougars were more abundant. The fraction of females in the harvest is arguably the statistic most widely used by managers to monitor changes in cougar populations (Cooley et al. 2011). However, our analysis revealed no significant correlation between this metric and either annual female survival or annual abundance in the OSCMU,

possibly because this index combines a variable fraction of non-reproductive sub-adult females with adult females. Anderson and Lindzey (2005) noted that the sex ratio of harvested cougars alone is of limited value in identifying population change, but when combined with age structure, both provide a more reliable index to population change. This was substantiated by our findings that at least for the OSCMU population, the percent of the harvest >6 years was positively correlated with annual female survival. However, this metric generally served as a proxy for the age structure of the population and was likely indicative of a population that has experienced several years of high survival and a greater proportion of more fecund females in the population.

In the MCMU, overall annual harvest mortality was principally influenced by male annual harvest mortality, suggesting that males were more heavily targeted than females in the MCMU. We further observed a positive correlation between the percentage of permits filled and annual survival overall but also independently for both female

Figure 4. Significant correlations between A) % permits filled and annual abundance, B) % of harvested cougars >6 years old and overall annual survival, C) % of harvested cougars >6 years old and annual male survival, and D) % of harvested cougars >6 years old and annual female survival, for the Oquirrh-Stansbury Cougar Management Unit, 1997–2012, Utah, USA.

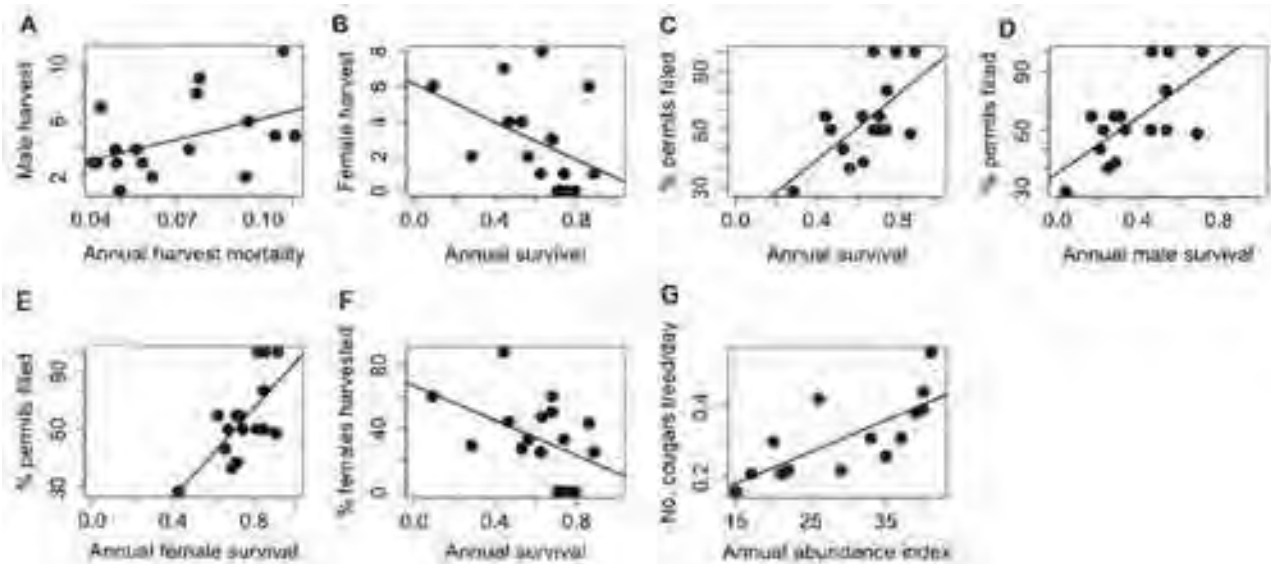

Figure 5. Significant correlations between A) male harvest rate and annual harvest mortality, B) female harvest and annual survival, C) % permits filled and overall annual survival, D) % permits filled and annual male survival, E) % permits filled and annual female survival, F) % females in the harvest and annual survival, and G) no. cougars treed/day and annual abundance for the Monroe Cougar Management Unit, 1996–2012, Utah, USA.

and male survival. This relationship indicates that hunters were more successful when annual cougar survival was high for the population as a whole, but also for females and males separately. The number of females harvested and the fraction of females in the harvest were negatively correlated with annual survival, suggesting that in this management unit, both statistics are relevant and their use is justified as the most widely used harvest index to monitor changes in cougar populations (Cooley et al. 2011). One of the more surprising results was the strong positive relationship between the number of cougars treed per day during the pursuit-season and the index of minimum annual cougar abundance on the MCMU. This index was arguably independent from harvest data because it is derived from the success of non-lethal pursuit permits. Choate et al. (2006) reported a weak ($P=0.13$) correlation from the same unit that was derived in the same manner but for a much shorter time span (6 years). As discussed by Whittaker and Wolfe (2011), this pursuit index is a catch-per-unit-effort estimator, and although easily obtained, this index is subject to several assumptions including demographic and geographic independence and constant catchability throughout the period of data collection. The latter assumption may be unrealistic because it implies that cougars do not learn to avoid capture. Despite these limitations, the relatively low cost of obtaining this index via phone surveys of sportsmen warrants further investigation and refinement.

MANAGEMENT IMPLICATIONS

Using harvest statistics that are already commonly collected from hunters in the state of Utah to determine harvest quotas for cougars was justified by our analyses. Specifically, the total number of females harvested and the fraction of females in the harvest were negatively correlated with annual survival; managers are right to pay particular attention to these harvest

statistics for monitoring cougar populations. In the MCMU, the percentage of permits filled was also a good proxy to changes in annual survival, annual female survival, and annual male survival. The highest correlation between cougars treed/day and the annual abundance of cougars suggests that pursuit indices may be an informative metric for wildlife managers to determine cougar population trends in intensely harvested management units. These harvest statistics may be suitable for cougar management units that have a similar hunting management regime as MCMU, with hunting being the predominant source of mortality.

In the OSCMU, the percentage of cougars in the harvest >6 years of age was correlated to overall annual survival, annual female, and male survival making them useful for monitoring changes in the demographics of cougar management units where harvest is not the only dominant cause of death (Wolfe et al. 2015). In such units, the percentage of permits filled tracked changes in annual cougar abundance, suggesting that this metric is a good indicator of population abundance in units that are not under intense harvest pressure.

Ideally, managers should also keep track of change in demographic rates, specifically survival and abundance, in key harvest management units that display contrasting harvest and mortality regimes. Our results illustrate the value of long-term data collection and suggest the possibility of expanding the scope of such comparisons to additional management units. Because the OSCMU and MCMU were subjected to contrasting mortality regimes (Wolfe et al. 2015), our results could be expanded to additional management units that share either the OSCMU or the MCMU characteristics. Ultimately, we suggest this analytical framework be extended to other harvested carnivore species for which harvest indices are available. When demographic information is available for certain harvest

management units, correlations between harvest indices and demographic rates can be used to assess which harvest indices are better proxies to changes in survival, abundance, and population dynamics.

ACKNOWLEDGMENTS

Logistical support was provided by the United States Forest Service, Fish Lake National Forest, and the United States Department of Agriculture, Wildlife Services, National Wildlife Research Center. This work relied to a great extent on the dedication of outstanding houndsmen (C. Mecham, M. Mecham, B. Bateman) and pilots (C. Shaffer, C. Hunt, and S. Biggs). D. L. Mitchell and C. Hendrix also contributed field assistance, and R. T. Skirpstunas conducted necropsies at the Utah Veterinary Diagnostic Lab. We are also grateful to K. D. Bunnell, A. J. Neville, and K. Rasmussen for advice and technical support. We are thankful to D. N. Koons for comments on earlier versions of the manuscript. Principal funding was provided by the Utah Division of Wildlife Resources, Kennecott Utah Copper Division of the Rio Tinto Mining Company, and the Utah National Guard.

ACKNOWLEDGEMENTS

This plan represents the efforts of many people throughout Idaho. Sincere appreciation is extended to the hundreds of concerned Idaho citizens who attended public meetings or workshops, reviewed early drafts of the plans, or wrote or telephoned the Idaho Department of Fish and Game to make their views known. Appreciation is also extended to Stephen Mealey, Director, for his efforts to bridge the gap among a divided constituency regarding black bear management. The Department's wildlife staff, led by Steve Huffaker, provided additional direction, and Regional personnel did an outstanding job reviewing the plans in addition to completing their regular duties. The Department's black bear species management committee (Wayne Wakkinen, Steve Nadeau, Neil Johnson, Jeff Rohlman, Bruce Palmer, Dave Koehler, Mike Scott, and John Beecham) contributed to this planning effort. Debra Martindale and Dan Maxwell produced the graphics.

Appreciation is also extended to the following individuals who donated considerable time and effort in developing the planning process and for identifying specific issues, solutions, and decision criteria. Their assistance was extremely helpful and constructive:

BLACK BEAR STEERING COMMITTEE

FOREWORD

Preserving Idaho's wildlife resources and hunting heritage will require cooperation from the citizens that are interested in black bears. This plan will provide the framework for the Department's management efforts for black bear and a solid foundation for ensuring the continued existence of viable black bear populations.

Many persons provided invaluable input to the Department during the development of this plan. A 9-member steering committee was formed early in 1998. Their charge was to propose a process for developing this plan that would involve a diversity of viewpoints regarding black bear management in Idaho. As a result of their efforts, a 20-member black bear planning team, composed of representatives from sporting interests and the general public, was convened on June 4, 1998. The planning team identified issues and strategies relevant to this plan and the decision criteria that would be used to evaluate the various management alternatives available to the Department.

The planning team identified several issues they believed the Department should address in this plan. Major issues included:

1. Methods of take
2. Management based on biological and/or sociological considerations
3. Management should be in the best interest of black bears
4. Provide for more flexibility to manage at the local or data analysis unit (DAU) level
5. Consider the impact of black bears on deer/elk populations
6. Develop criteria to indicate when black bears are abundant
7. Methods of gathering public input on black bear management program

General, recurring themes focused on customizing management to fit goals and objectives at the DAU level, using sound biology to establish those goals, improving public education and involvement, and evaluating biological and sociological implications of our management decisions. Decision criteria suggested by the planning team emphasized three general areas. They included:

1. Will the action have the desired effect?
2. Is the action feasible from a cost-effective and logistical standpoint?
3. What are the social implications?

Where appropriate, the Department has attempted to incorporate these suggestions into this plan.

1999-2010 BLACK BEAR MANAGEMENT

INTRODUCTION

Wildlife managers juggle many diverse issues in attempting to integrate the needs and desires of humans with the biological needs of black bears. The Idaho Department of Fish and Game periodically develops management plans that establish the Department's philosophy and management direction for black bears and serve as guidelines for setting black bear hunting seasons. This plan is the fourth plan written since 1980. Each plan represents a step forward in the development of a management program that will ensure the long-term viability of black bear populations and provide recreational opportunity for hunting and non-hunting resource users. Specific objectives are included in this plan to identify management direction for each DAU, which reflects the ecosystem management principle that predator and prey management should be linked to ensure a reasonable balance among species. The specifics regarding how the department will attempt to reach those objectives will be dealt with annually in the regular season setting process.

The Department is currently undergoing a transition in terms of responding to its constituency - the people of Idaho. As a result of current sociological trends, decisions about how the Department manages black bears have become very controversial. Many of Idaho's citizens disagree on issues such as spring black bear hunting seasons and using bait or hounds to hunt black bears. Although these issues have significant potential for influencing the general public's perception of the acceptability of hunting, in most cases they have only minimal biological impact on black bear populations. Habitat fragmentation and loss is far more important to the long-term survival of black bear populations and is, unfortunately, often lost in the debate over hunting methods.

The popularity of black bear as a big game animal to hunters using a variety of hunting techniques, and the concerns of some citizens about the use of those methods of take have combined to generate some controversy in the management of this species. This plan represents an attempt by the Department to consider the viewpoints of all Idahoans on how black bears should be managed in the state.

MANAGEMENT HISTORY

Although the black bear was classified as a game animal in 1943, with a bag limit of 1 per year, few protective laws were passed until 1973. Beginning in 1973, resident hunters were required to have a tag in their possession while hunting black bears in those Game Management Units (GMU) in northern Idaho that had summer hunting closures. Resident black bear hunters in much of southern Idaho, where seasons remained open to year-round hunting, did not need a tag. Non-resident black bear hunters were required to have a tag in all GMUs in the state.

In 1975, the Department allowed hunters to take 2 bears in 3 GMUs. The bag limit was increased to 2 bears in 21 additional GMUs in 1977. Females accompanied by cubs were protected during the spring season from 1973 through 1982. In 1983, females accompanied by

cubs were protected during the spring and fall seasons. Year round hunting seasons and 2 bear bag limits were eliminated in 1986.

The Department has relied on two primary methods to collect black bear harvest data: 1) the mandatory check and report program implemented in 1983, and 2) the annual telephone harvest survey. The mandatory check-in report program requires the hunter to bring the skull and hide (1992) of their harvested black bear to an official check point within 10 days of the kill date and to fill out a harvest report form. In most cases a premolar tooth is extracted from the skull for aging. Pertinent data including kill date, location of kill, and method of take are recorded on the harvest form. Compliance with the mandatory report program is unknown.

The telephone survey of hunting license holders provided a second estimate of the black bear harvest. This survey contacted approximately three percent of the black bear tag holders and it provided information from successful and unsuccessful hunters. A statewide harvest estimate, recreation days, and hunter success rates were estimated. The black bear portion of the harvest survey was discontinued in 1996 due to funding cutbacks.

POPULATION BIOLOGY

In 1972 the Department initiated a black bear research project to collect biological data for a comprehensive management program. Six black bear populations were studied. These studies were designed to determine the status of each population, although data were also collected on food habits, physical condition, denning requirements, activity patterns, and habitat use patterns. Research information collected from black bear populations in lightly hunted and heavily hunted areas was used by Department biologists to develop harvest criteria and to interpret harvest data collected through the mandatory check program.

Detailed information about black bear biology in Idaho can be found in a book authored by John Beecham and Jeff Rohlman titled: "A Shadow in the Forest - Idaho's Black Bear." The University of Idaho Press published this book in 1994.

HABITAT MANAGEMENT

Black bear distribution in Idaho corresponds closely to the distribution of coniferous forests. North of the Snake River plain they are found throughout the forested mountains and foothills. Few black bears occur south of the Snake River, except in southeastern Idaho. About 75% of black bear habitat in Idaho is administered by the US Forest Service; 20% is controlled by private interests; and the rest is administered by other agencies, such as the Bureau of Land Management, Idaho Department of Lands, and Idaho Department of Fish and Game.

Idaho has approximately 30,000 square miles of black bear habitat. Although it is difficult to estimate the size of black bear populations, Department research has shown that black bear densities vary among areas in Idaho. The black bear social system limits density to 1.5 to 2 black bears per square mile in the best habitats. However, even in good quality habitats, many factors can influence the size of the black bear population in any given year. Several years of

poor berry crops can result in reduced cub production and increased mortality of sub-adult black bears. Heavy hunting pressure can also reduce the population below the carrying capacity of the habitat.

Forest management practices, wildfires, and plant succession influence black bear habitat quality. The black bear's diet is primarily grasses and forbs during the spring and early summer. By mid-July, they begin adding fruits such as huckleberries, wild cherries, buffalo berries, hawthorn, and mountain ash to their diet. Approximately 10% of the black bear's annual diet is animal matter: insects comprise about 9% and vertebrates make up the remaining 1 percent. In many situations partial removal of the forest overstory helps black bear because it opens up the forest canopy and allows for increased plant production on the forest floor. However, increased human access into black bear habitats makes black bears more vulnerable to hunters. This factor partially offsets the benefits of logging activity.

Department-sponsored research on black bear habitat use patterns suggests that the following actions will maintain or enhance black bear habitat in areas where logging has been proposed.

Recommendations:

1. Minimize soil disturbance in areas where berry-producing shrubs are abundant by using rubber tired vehicles or logging over snow cover.
2. Use selection cuts to maintain black bear security cover. Retain 40-70% canopy coverage when huckleberry (Vaccinium sp.) is abundant in the understory.
3. Maintain relatively dense pole-sized timber stands in the overall vegetative mosaic on north and east aspects for use as bedding areas.
4. Retain some mature trees in logged areas to enhance their use by female black bears with cubs.
5. Maintain aspen stands in the overall vegetative mosaic.
6. Broadcast-burn slash or leave it untreated and minimize soil scarification to prevent damage to rhizomatous food plants.
7. Create leave patches or leave strips within cutting units for security cover. Clear-cuts should be small and have irregular borders to provide security cover.
8. Maintain a mix of different-aged cutting units to influence black bear density and distribution in an area.
9. Logging roads should be located out of creek/river bottoms where significant black bear foods occur.
10. Area closures to motorized vehicles should be implemented to reduce black bear mortality rates and increase habitat effectiveness.

Habitat loss and fragmentation due to human encroachment also has a subtle, yet permanent, impact on the long-term viability of black bear populations. Ultimately, the accelerating pace of habitat fragmentation and loss will dictate how long we can maintain black bear populations in some areas of the state. However, the prognosis for the future of black bears in much of the state

remains positive because a majority of the land base is publicly owned. As long as we continue to consider the wellbeing of Idaho's wildlife resources when making habitat management decisions, those habitats will continue to support viable black bear populations.

POPULATION MANAGEMENT

The vulnerability of black bear to harvest varies greatly because of differences in habitat and access. Bears are less vulnerable where cover is dense and expansive. They are particularly vulnerable in highly roaded areas and habitats that provide only patches of security cover. This often results in populations with fewer adult black bears, especially males.

The sex and age of a black bear also affects its vulnerability to harvest. Adult males are typically most vulnerable because they are bold (often use open areas) and have larger home ranges. Consequently, the adult male segment of a population is the first to be reduced under hunter pressure. Sub-adult males are slightly less vulnerable. Females are least vulnerable, especially if accompanied by cubs. A low percentage of adult males (≥ 5 years old) in the harvest may be an indication of over-harvest.

Hunting pressure affects harvest rate, which affects age structure, sex ratios, and densities of black bear populations. As harvest rates increase, the proportion of sub-adult black bears (those less than 4 years old) in the harvest typically increases, whereas the proportion of adult males declines. At higher harvest levels, the proportion of females in the harvest increases, and harvest may result in a population decline if a large area is affected or if there are no reservoir areas nearby to produce dispersing sub-adult black bears. In reservoir areas, black bear populations are limited by the capacity of the habitat to support black bears and their social structure. Some species compensate for excessive adult mortality by producing more young. However, black bears do not respond in this manner. In fact, high adult mortality results in a younger age population and lower productivity (average number of young per litter). Young male black bears disperse from their mother's home range when they are 1.5 to 2.5 years old and often travel long distances to occupy vacant habitat. However, young female black bears rarely disperse far. As a result, black bear populations far from reservoir areas are slow to recover from over-harvest.

The ages of black bear captured during Department-sponsored research projects indicated that lightly hunted populations had a high ratio of adults to sub-adults (70:30), a high percentage of adult males (35%), and a median age of 7.5 years. Data collected from heavily hunted populations showed adult:sub-adult ratios favoring sub-adults (40:60), fewer adult males (21%), and a median age of 2.5-3.5 years. Studies of black bear populations in Alaska, Virginia, and Arizona showed similar relationships between lightly and heavily hunted populations.

Department research demonstrated that age and sex data derived from trapping was closely correlated with that from the harvest. It follows, therefore, that harvest criteria have potential for monitoring population status.

HARVEST CHARACTERISTICS

Black bears in Idaho are long-lived, they mature late (4-7 years old), and they have low reproductive rates. Short-term changes in the size of black bear populations are related to changes in birth rates associated with the availability of nutritious foods, especially late summer and fall berry production. Long-term trends are directly related to changes in habitat quantity and quality.

The reproductive characteristics of Idaho black bears suggest that harvest rates must remain low to ensure sustainable harvest goals. Unfortunately, no easy or inexpensive methods exist for assessing the status of black bear populations. Therefore, Department biologists must rely on indirect measurements (harvest data) to evaluate the effectiveness of management actions. These limitations re-emphasize the need to implement conservative management strategies for black bear.

During the past planning cycle, black bear tag sales have increased slightly for resident black bear hunters and decreased for non-resident hunters (Figure 1). At least part of the increase observed for resident hunters can be attributed to increased sales of Sportsmen Pak and Deer, Elk, Bear Pak licenses which include a black bear tag. The decrease in non-resident black bear tag sales (75% since 1987) is probably associated with increased costs for those black bear tags (\$40.50 in 1987 and \$226.50 in 1998). The sale of baiting permits (\$1.50) was initiated in 1993. Sales of these permits increased from 1,195 in 1993 to 1,349 in 1995 and have since declined to about 1,200 in 1998. The sale of hound hunter permits has increased from 988 in 1993 to 1,257 in 1998 (Figure 2).

Black bear harvest during the last 12 years shows a cyclic pattern that is relatively stable or slightly increasing (Figures 3 and 4). During the 1986-1992 planning period, hunters took an average of 1,277 black bears. During 1993-1997, an average of 1,355 black bears was harvested. The Panhandle Region accounted for 34% of the harvest in the last planning period; 28% came from the Clearwater Region; 22% from the Southwest Region; 10% from the Salmon Region; and the remaining 7% came from the Magic Valley, Southeast, and Upper Snake Regions.

The emphasis of the 1992-2000 bear plan was to stabilize total harvest and reduce the harvest of female black bears. Management actions implemented by the Department resulted in a short-term reduction in total harvest and a shift in the seasonal harvest of bears, but did not influence the sex ratio in the harvest (Figures 5 and 6). Analysis of the harvest data suggests that shortening the spring hunting season did reduce the female harvest. However, eliminating hunting opportunity in early September (September 1-14) was ineffective in reducing total female harvest during September. Female black bears appear to be more vulnerable to harvest in the fall hunting season because many females are no longer accompanied by the previous years cubs and they have high energy demands.

The average number of days hunters used to successfully harvest a bear was less than 7 days for those using bait, hounds, incidental, or still hunting methods. Shortening long, 2-3 month spring and fall hunting seasons by 1-3 weeks would not affect the length of time that most hunters spend in the field pursuing bears. Analysis of harvest data suggest that shortening seasons

results in short-term reductions in harvest, but hunters quickly learn to adapt and harvest levels increase.

Black bear tag holders use 4 primary methods for harvesting a black bear: spot and stalk (still hunting), hound hunting, hunting over bait, and incidental hunting (hunting black bears while primarily engaged in some other activity like deer or elk hunting, wood gathering, fishing, or camping). During the 1986-1991 planning cycle and the 1992-2000 cycle, still hunters took slightly more black bears than hunters using other methods (Figure 7) did. However, bait and hound hunters experienced the highest success rates. No differences were observed in the percentage of female bears taken by hunters using bait (28%), hounds (35%), incidental (36%), or still (35%) hunting methods.

1999-2010 GOALS AND OBJECTIVES

Goal: To ensure the long-term viability of black bear populations in Idaho and to provide recreational opportunity for the hunting and non-hunting public.

Objectives:

1. To establish harvest objectives and management approaches for each DAU that reflects the unique characteristics of that area.
2. To distribute recreational opportunity throughout black bear habitat in a manner that is consistent with population objectives for each DAU.
3. To improve harvest information by improving compliance with the mandatory check and report program and by implementing a telephone or mail survey to generate information on hunter numbers, hunter success rates, hunter effort. Improving compliance level with the mandatory check program will provide insight into the non-reporting bias.
4. To use an adaptive management approach in developing harvest goals and objectives in select DAUs as a means to further evaluate management descriptors. In some DAUs, harvest objectives will be set to significantly increase harvest. In other DAUs, harvest pressure will be significantly reduced to serve as a comparison of the sensitivity of the harvest descriptors.
5. To monitor the response to changes in the black bear harvest using our biological criteria and take steps to increase or reduce harvest when data indicate the opportunity or need.
6. To manage black bears to reduce conflicts among competing user groups.
7. To consider initiating research to:
 - a. Develop a long-term population monitoring technique.
 - b. Establish the link between harvest criteria and the characteristics of the standing population by determining age- and sex-specific vulnerability to different harvest techniques.
 - c. Determine black bear mortality patterns and reproductive potential.
8. To work with the Outfitters and Guides Licensing Board to set outfitter quotas in DAUs where a harvest reduction is needed. This will include evaluating new license and renewal applications.

DECISION ELEMENTS

TELEPHONE SURVEY

Harvest data are the primary source of information used to make management decisions. Harvest trends derived from the mandatory check and report system are difficult to interpret without supporting data such as changes in hunter numbers or effort.

Therefore, the Department will develop an enhanced telephone survey that specifically targets black bear tag holders. Sampling effort will be focused on obtaining reliable harvest estimates at the DAU level, estimates of hunter numbers and effort expended by successful and non-successful hunters, and an estimate of compliance with the mandatory check and report requirement.

DAUs selected for intensive monitoring during this planning period will be sampled at a higher rate in an effort to evaluate the sensitivity of our harvest criteria.

MANDATORY CHECK AND REPORT

This program continues to provide most of the data that are collected on black bear in Idaho. Although compliance is unknown, we will continue to rely on this program to provide the data we need to evaluate harvest trends.

HARVEST CRITERIA

No economically feasible methods are available to monitor the abundance of black bears in Idaho. As a result, Department biologists have relied on a variety of indirect measures of harvest data to assess population trends. Management decisions are based upon harvest data collected through the mandatory check and report program. Although population trends are difficult to ascertain from harvest data, it is the only information available to biologists that can be collected in a systematic manner designed to minimize confounding variables such as hunter numbers, hunter effort, and season structure and length. When these variables are standardized or at least measured, harvest trends may have value in determining the effects of management actions.

During the last planning period (1992-2000), the Department used the percent females in the harvest, median age of harvested females and males, and, in limited areas, bait station survey results to monitor population trends. Specific criteria were established to indicate over-harvest and a desired level of harvest.

Further analysis of our harvest data suggest that median age is a useful tool to distinguish lightly hunted or unhunted populations from those that are hunted at moderate to heavy levels. However, median age does not appear to be very sensitive to population changes on a year-to-year basis. As a result, the Department is eliminating median age as a harvest criterion and will monitor the percent of males ≥ 5 years old in the harvest on a 3-year running average (Table 1).

This indicator appears to be a more sensitive measure of population harvest levels and is supported by data collected by the Department during 12 years of research on black bear ecology. The Department's bear team also recommended that the minimum threshold for adult males ≥ 5 years old in the harvest should not drop below 20% on a 3-year running average. However, the Department will try to evaluate the usefulness of this criterion in describing the status of a population, during this planning cycle, by attempting to push this threshold below 20% on an experimental basis in one or more DAUs. Harvest trends will be manipulated in other DAUs to further evaluate these population descriptors.

Table 1. Harvest statistics for black bears in Idaho, 1993-1997.

All DAUs	Total Harvest	Percent Female	Percent Males ≥ 5	3-Year Average Males ≥ 5
1993	1,126	35	39	
1994	1,304	34	34	
1995	1,331	34	34	35%
1996	1,522	33	32	33%
1997	1,552	34	29	32%
Total	6,835	34	33	

The Department will implement a 3-tiered set of criteria to evaluate population trend in various DAUs (Table 2). The Department will continue to monitor trends in percent females in the harvest, calculated on a 3-year running average.

Table 2. Harvest descriptors for black bear in Idaho.

Criteria	Light Harvest	Moderate Harvest	Heavy Harvest
Percent Females	<30%	30-40%	>40%
Percent Males ≥ 5	>35%	25-35%	<25%
Bait Station Survey	Increasing	Stable	Decreasing

We also recognize that certain areas in Idaho provide extensive secure habitat (reservoirs) for black bears. Unroaded and/or wilderness areas are prime examples. Hunting pressure is light in these core areas, resulting in relatively high percent males ≥ 5 years old and low percent females in the harvest. Because population turnover is low, there is little vacant habitat and young black bears, especially males, are forced to disperse into surrounding less secure habitats where harvest rates are often high. These young dispersing males will dominate the harvest statistics in the surrounding areas. Age criteria for the DAU may be violated in these areas, even though the core or reservoir population is secure and will continue to supply a surplus of dispersing black bears. Current harvest criteria may not apply in these situations. The key is to ensure that the

harvest remains focused on the dispersing black bears and does not compromise the reservoir population. In such cases, management direction will be based on the Department's discretion and interpretation of a variety of factors including perceived black bear population status, social considerations, and other factors (i.e., weather patterns, changing road access, etc).

In some DAUs, black bear harvest is consistently low, resulting in small samples from which to monitor harvest parameters. This may lead to inaccurate conclusions. Hence, harvest criteria will be applied only to DAUs in which average annual harvest is at least 30 black bears. When harvest is <30 black bears, the criteria do not apply, and management decisions will be based on professional judgment.

SEASON FRAMEWORK

A variety of factors may influence black bear seasons locally. Increasing urbanization in black bear habitat, habitat characteristics, predation on deer and/or elk, and road densities are factors that will be considered on a local basis in the season setting process.

Black bear seasons will be structured to meet the management goals and objectives for each specific DAU. The Department recognizes that too much variation among DAUs in season length and timing, or in allowable methods of take, can create confusing, complex rules. It is the intent of the Department to minimize this complexity by standardizing seasons statewide in a manner consistent with the goals and objectives of the various DAUs.

BLACK BEAR - HUMAN CONFLICTS

The Department recognizes that black bears will occasionally damage private property, prey on domestic livestock, and jeopardize public safety. The improper storage of human foods and garbage is often the primary factor leading to bear-human conflicts. Other factors include inadequate supplies of natural foods, injuries, and, in the case of sub-adult bears, inexperience in locating natural foods. Human encroachment into black bear habitat is a major cause of many depredation problems. The Department has the responsibility for controlling black bears in nuisance and human safety situations. The U.S. Department of Agriculture's Wildlife Services program (Wildlife Services) may handle these complaints at the request of the Department, if mutually agreed upon by both parties. Wildlife Services has the responsibility for handling black bears involved in livestock depredation problems, including apiaries. The Department may handle these complaints at the request of Wildlife Services, if mutually agreed upon by both parties. Guidelines for handling bear-human conflicts can be found in Appendix I.

BLACK BEAR - DEER\ELK RELATIONSHIPS

Extensive studies of black bear food habits throughout their range clearly show that vertebrates (primarily deer and elk) make up a very small part of the bear's yearly diet (<2%). Black bears rarely prey on adult deer or elk. However, black bears do prey on deer and elk neonates (fawns and calves) in some localities where favorable conditions exist for taking these animals.

The *fact* of predation (black bears do kill and consume deer fawns and elk calves) has never been disputed in discussions about black bear predation on other big game species. The major area of debate has involved the *effect* of that predation on populations of deer and elk.

Predator-prey interactions are extremely complex and involve many factors such as weather conditions, status of the prey population, availability of alternate prey, presence and density of other predators, and habitat conditions. As a result, it is difficult to determine what the effect of predation may be in any specific situation. In situations where the prey population is at or near the carrying capacity of its habitat, predation on deer or elk neonates probably has very little effect on prey population size or growth rate, and efforts to regulate predator numbers will not result in a larger prey base. However, when adverse weather or habitat deterioration results in a prey population decline, predation may increase the rate of decline and even result in a lower population level than would occur in the absence of predation. If issues of scale, logistics, and economics allow, reducing predator numbers in this situation may decrease the rate of decline and provide some benefit to the prey population.

The Wildlife Manager must evaluate all of these factors and the prevailing social environment before determining a course of action that serves the best interests of both the predator and its prey.

CONFLICTS WITH GRIZZLY BEARS

The U.S. Fish and Wildlife Service classified the grizzly bear as a “threatened” species in 1975. The Department currently restricts use of dogs and bait to hunt black bears in grizzly bear recovery areas (Units 1, 62, 62A, and part of 61). This approach, in conjunction with intensive public relations work and selected road closures, seems to be effectively reducing grizzly bear mortality. This strategy will be continued and its effectiveness monitored. Additional steps that could be taken if deemed necessary include:

1. Separating black bear season from general big game seasons in grizzly bear recovery areas.
2. Require hunters hunting in grizzly bear recovery areas to view a bear identification video.
3. Implementing controlled black bear hunts in grizzly bear recovery areas to limit the number of black bear hunters.
4. Changing or eliminating black bear seasons to reduce grizzly bear mortalities in grizzly bear recovery areas.

At this point in time, we do not recommend incorporating these steps in our black bear management program because the current approach seems to be effective. If the current program proves inadequate, we will consider the actions listed above. Additionally, controlled hunts similar to the one implemented in DAU 1A will be considered in seasonally unoccupied areas currently designated as grizzly bear recovery areas.

HOUND HUNTING

Approximately 1,100 hunters in Idaho practice hound hunting and they harvested about 16% of the bears taken during 1993-1997.

Hound hunting permits will be required for every member of a hound hunting party during take seasons. This permit requirement applies to residents and non-residents, but does not apply to the clients of licensed outfitters or up to 4 immediate family members of a permit holder. Immediate family is defined exclusively as the parents, spouse, children, and grandchildren of the hound hunting permit holder.

A quota on non-resident hound hunters will be maintained during this planning period for the black bear take season. In those areas where the Department's management objective is to increase the harvest, the Department may consider liberalizing or removing the quota. The Department will also consider removing the quota during the dog-training season. The Department will continue to prohibit hound hunting in designated grizzly bear recovery areas.

HABITAT MANAGEMENT

Because black bears are an important wildlife resource, the Department desires to elevate their profile among wildlife biologists, land managers, and the public. Bears and their habitat will play a more significant role in land management decisions, and good black bear habitats will be managed as such. Biologists will use specific knowledge of black bear habitats to develop interim guidelines and will provide technical support to public land management agencies and private corporations to identify and manage important black bear habitats.

The Department recognizes that valuable black bear habitat has been inundated, and associated wildlife populations have been lost, because of hydroelectric projects in Idaho. The Department will seek funding for full compensation for the loss of this habitat and associated wildlife from the Bonneville Power Administration under the Columbia Basin Fish and Wildlife Program, and from Idaho Power Company and other hydropower developers and responsible project operators under other programs.

PUBLIC OPINION SURVEYS

Current information on the public's perception of our black bear management program can be obtained from periodic surveys of public attitudes. The Department will sponsor or conduct surveys, designed by professional social scientists, to gather pertinent information that will enhance the Department's ability to manage black bears.

LAW ENFORCEMENT

During the public review process, the Department documented a strong desire by the public for the aggressive prosecution of all fish and game violators and for stiffer penalties. The Department will continue to encourage the public to use the Citizens Against Poaching (CAP)

program to report violations. We will continue to work with legislators, prosecutors, and judges to achieve significant penalties for those individuals convicted in the courts. The Department will also use undercover (covert) operations to address this problem.

PUBLIC EDUCATION

It is apparent that the public was eager to have more information about black bear biology and wildlife management principles in general. The Department will continue to provide information on the consumptive and non-consumptive values of black bears to the public. In 1994, the Department published a book based on Department-sponsored research on black bear ecology. That book, titled "A Shadow in the Forest - Idaho's Black Bear," is available at local bookstores. The Department also published a teacher's guide in 1995 that provides information on the biology of black bears and activities to help students learn important concepts about ecological factors affecting Idaho black bear populations.

WATCHABLE WILDLIFE

There is some public demand to view black bears in their natural environment. Therefore, the Department will provide opportunity in portions of some Units for viewing black bears. The Department may select areas for non-consumptive use where: 1) area closures on black bear hunting currently exist to protect threatened grizzly bear populations or to accommodate research; 2) road access exists into relatively open habitats where black bears can easily be seen; and, 3) where conflicts with other resource users in the area are minimal.

BAITING

About 1,250 hunters in Idaho used baiting as a method of take, and they were responsible for approximately 18% of the bears harvested during 1993-1997. Over 90% of the harvest by hunters using bait occurred during the spring season.

The Department will continue to allow hunters to use bait in those DAUs where the practice is consistent with the management objectives for that area. However, the Department will continue to prohibit baiting in designated grizzly bear recovery areas. The Department will also consider changes in the baiting rules that will reduce or alleviate conflicts between hunters using baits and campers and hikers, and in areas with nearby summer home developments. IDFG-recommended standards for baiting can be found in Appendix II.

STATEWIDE MANAGEMENT PROGRAM

Idaho is divided into 5 areas for purposes of managing black bear populations (Figure 8). Area 1 includes habitats that vary from dense, semi-coastal forests to patchy forest habitats along dry river breaks. Abundant road access and proximity to human population centers characterize Area 1 GMUs. Area 2 includes habitats similar to Area 1, but not as accessible by road and not as close to major population centers. Area 3 has limited access and much of it is officially designated as Wilderness. Area 4 includes a variety of habitats that are generally dry shrub and grass types with few berry-producing plants. The livestock industry is a major resource user of public lands in Area 4. Area 5 includes most of the irrigated lands in southern Idaho and the drier, desert portions of the state. Habitat quality in Area 5 is marginal for black bear and few black bears occur there. Based on similarities in habitat, road access, and proximity to urban population centers, 3 of the 5 black bear management areas (Area 1, 2, and 4) are divided into smaller groups, DAUs, to facilitate analysis of harvest information (Figure 1). The DAU concept was developed in 1985 to enhance the Department's ability to interpret harvest data and to simplify the rules regulating black bear harvest.

MANAGEMENT ACTIONS

The Department has two basic options available to influence harvest rates: adjusting 1) hunting opportunity (season length and timing), and 2) methods of take. Each approach has advantages and disadvantages and the preferred choice should be dictated by current conditions in the DAU and management objectives. First and foremost, management objectives must address the biological requirements of black bears. Once those are satisfied, harvest regulations are developed that reflects differences in vulnerability, hunting pressure, and road access among areas.

Season length and timing are ineffective approaches for regulating the total harvest of black bears. However, adjusting season length and timing can be an effective means of regulating harvest sex-ratios and in some cases, age structure. The vulnerability of black bears to hunting is influenced by extrinsic (weather, etc.) and intrinsic (seasonal behavior) factors. Adult males are the first bears to leave their winter dens, followed by sub-adult males and single females. Closing spring hunting seasons in early to mid-May focuses most hunting pressure on males and females unaccompanied by cubs or yearlings. It also provides additional protection for female bears accompanied by cubs-of-the-year because they are often the last bears to leave their winter dens. Adult males are the last bears to enter dens in the fall; females generally enter their dens in early to mid-October. As a result, late fall hunting seasons also focus hunting pressure on male black bears.

Regulating the methods of take that are used by hunters can be effective in adjusting total harvest, and potentially the sex and age composition of the harvest. Options available to the manager using this approach include: 1) unrestricted opportunity; 2) taking actions to reduce the efficiency of hunters using bait, hounds, or still hunting methods; and, 3) eliminating the activity as a legal method of take.

The Department will use one or more of the following management options as needed for regulating black bear harvest.

To increase harvest in a DAU:

- Maximize hunting opportunity.
- Increase bag limit to two black bears per year.
- Increase bag limit to one black bear in spring season and one black bear in fall season.
- Increase/eliminate non-resident hound quota.
- Increase spring season length - maximum allowed 4/1 - 6/30.
- Increase fall season length - maximum allowed 9/1 - 11/15.
- Reduce tag cost.
- Contract with the U.S. Department of Agriculture, Wildlife Services Division to kill black bears in areas where sport hunting is not effective in reaching management goals.

To reduce harvest in a DAU:

- Eliminate baiting as a legal method of take.
- Eliminate hound hunting as a legal method of take.
- Eliminate black bear hunting during D/E seasons.
- Eliminate spring season.
- Eliminate fall season.
- Allow baiting in fall only.
- Allow hound hunting 4/1 - 5/15 and 9/1 - 9/30.
- Close spring season on 5/15.
- Implement controlled hunts.

Harvest management objectives for each of the 21 DAUs is summarized in Table 3.

DAU 1A

Game Management Unit 1

DESCRIPTION

Black bear management is heavily influenced by grizzly bear management needs in this DAU as it includes parts of the Selkirk and Cabinet-Yaak Grizzly Bear Recovery areas. Consequently, this DAU has been closed to use of bait since 1984 and to the use of hounds since 1988. Since 1991, a small controlled hunt allowing use of hounds has been allowed in a portion of DAU 1A outside of these recovery areas. During 1993 the season was shortened from 108 to 80 days and has since been increased to the current 96 days.

In general, this DAU is characterized by dense conifer habitat types. Portions of the Selkirk, Cabinet, and Purcell mountain ranges are included in this DAU, with the broad Kootenai River Valley providing the only substantial agriculture area. Overall, DAU 1A contains some of the highest quality black bear habitat in Idaho.

Total harvest in DAU 1A has averaged 173 bears from 1993 to 1997. Mature males (≥ 5 years old) make up over 35% of the harvest. Harvest has increased significantly in the past 2 years. However, the percent of mature males and percent of females in the harvest has not changed and indicate a moderately harvested population.

MANAGEMENT OBJECTIVES

DAU 1A will be managed to maintain the light harvest targets of $>35\%$ age 5+ bears in the male harvest and $<30\%$ females in the total harvest.

1993 - 1997

SEASON

1993 - 1997

DAU 1B

Game Management Units 2, 3, and 5

DESCRIPTION

DAU 1B consists largely of developed and highly accessible areas. Mountains in this DAU are not particularly high or rugged. Depredations have been a substantial problem in this DAU, particularly in Unit 2, which consists largely of second-growth coniferous forest under private ownership. Unit 3 is typified by publicly owned coniferous forest with high road densities in close proximity to Coeur d'Alene. Unit 5 is similar to Unit 2 in the northern third, but the remainder consists largely of open agricultural land with stringers of coniferous forest. Much of Unit 5 is within the boundaries of the Coeur d'Alene Indian Reservation.

Use of baiting and hounds is substantial in DAU 1B. Thirty-five percent of the black bears harvested in this DAU are taken with one of these aids. Still hunting and incidental harvest accounted for 32% and 29% of the harvest, respectively.

Harvest in DAU 1B has averaged 83 bears from 1993 to 1997. The lower harvest associated with new season restrictions that began in 1993 has since returned to previous highs. Harvest increased significantly in 1996 and 1997, but the percent of mature males and mature females in the harvest has remained constant. Harvest statistics indicate a moderate to highly harvested population.

MANAGEMENT OBJECTIVES

To address depredation concerns, DAU 1B will be managed to maintain the heavy harvest targets of <25% age 5+ bears in the male harvest and >40% females in the total harvest.

DAU 1B

Total	449	40	26	

TOTAL HARVEST

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1C

Game Management Units 4 and 4A

DESCRIPTION

DAU 1C consists mainly of US Forest Service property and a belt of private property in Silver Valley. Much of this DAU has been burned by wildfires since the early 1900s. It is a popular hunting area for Coeur d'Alene and Silver Valley big game hunters. Road densities are moderate to very high.

This DAU has traditionally supported a substantial harvest for hunters using hounds. This type of use declined abruptly during 1992, concurrent with an increase in other categories. Only 11% of the black bears harvested in this DAU are now taken with the aid of hounds and/or bait. Still hunting and incidental kills made up 54% and 42% of the 1997 harvest, respectively.

Total harvest in DAU 1C has averaged 75 bears from 1993 to 1997. Mature males (≥ 5 years old) have shown a decline over the past 5 years and in 1997 the 3-year average was 20%. Mature females also have shown declines. Harvest has increased moderately in the past two years. Harvest statistics indicate a moderate to heavily hunted population.

MANAGEMENT OBJECTIVES

To test the validity of the bear harvest indicators, DAU 1C will be managed to maintain the heavy harvest targets of $<25\%$ age 5+ bears in the male harvest and $>40\%$ females in the total harvest.

1993 - 1997

SEASON

1993 - 1997

DAU 1D

Game Management Units 8A and 10A

DESCRIPTION

The first wave of timber harvest in this DAU occurred during the early 1900s and consisted mostly of removing the most commercially valuable timber species and largest trees. During the 1970s, timber harvest increased fairly dramatically, and new roads provided access to previously inaccessible areas. In 1971, Dworshak Reservoir flooded approximately 45 miles of North Fork Clearwater River corridor with slack water, permanently removing thousands of acres of prime low elevation winter range for big game and spring range for bears.

DAU 1D is three-quarters timberland and one-fourth open or agricultural lands and is bisected by canyons leading to the Clearwater River. The timberland is owned predominantly by Potlatch Corporation, IDL, and the USFS. Access is very good throughout the DAU and timber harvest occurs on most available timber ground. High open and closed road densities contribute to high vulnerability for big game species. During the 1980s and 1990s, timber harvest occurred on almost all available state and private land as demand and management of these lands intensified. Despite the reservoir, extensive logging along the river corridor improved winter range in this unit. South aspect forests were cleared to provide timber products and inadvertently provided quality berry brush fields and spring range for bears. The warm and moist maritime climate contributes to rapid plant growth and decay, providing optimal habitat conditions for bears.

Bears occasionally cause damage to fruit trees and apiaries throughout the agricultural lands of this DAU.

MANAGEMENT OBJECTIVES

DAU 1D will be managed to maintain the heavy harvest targets of <25% age 5+ bears in the male harvest and >40% females in the total harvest.

1993 - 1997

SEASON

1993 - 1997

DAU 1E

Game Management Units 8, 11, 11A, and 13

DESCRIPTION

This DAU contains portions of the highly productive Palouse and Camas prairies, as well as the canyon lands along the Snake and Salmon rivers. Currently, virtually all non-forested land in Units 8 and 11A is either tilled or grazed, and only small, isolated patches of perennial vegetation remain. Cattle grazing occurs on almost all of the available timber ground.

This DAU contains mostly private and some publicly owned land. Unit 11 is mostly private land except for the Craig Mountain Wildlife Management Area (CMWMA) along the Snake and Salmon rivers. Unit 13 has been mostly under private ownership since settlement, and is managed mostly for agriculture and livestock.

Habitat productivity varies widely throughout the DAU with steep, dry, river canyon grasslands having low annual precipitation, to higher elevation forests having good habitat productivity and greater precipitation. Late successional forest cover types have become fragmented within the DAU. Various berry species occur in canyon draws and hillsides providing a diversity of fall foods for bears. Road density is moderate, and access is restricted in many areas.

Bears occasionally cause damage to fruit trees and apiaries located near canyon draws and forest stringers.

MANAGEMENT OBJECTIVES

DAU 1E will be managed to maintain the heavy harvest targets of <25% age 5+ bears in the male harvest and >40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1F

Game Management Units 14, 15, 16 and 18

DESCRIPTION

The prairie regions of this DAW were converted to agriculture & ranching by early settlers. In 1862, gold was discovered near the current location of Elk City in Unit 15. After the readily available gold was depleted, miners turned to dredging activities where rivers ran through meadows. Crooked, American, and Red rivers were channelized and rerouted several times during the extraction processes, which continued commercially until the 1950s. Logging began with mining activities to supply wood for the mines, but in the 1940s, logging activities became commercial and resulted in an extensive network of roads throughout a large portion of this DAW. In 1964, with the passage of the Wilderness Act, a small portion of Unit 16 was designated as a part of the Selway-Bitterroot Wilderness. In 1978, portions of Units 14 and 15 were included in the Gospel Hump Wilderness. Unit 18 is two-thirds public land with the remaining private land located at lower elevations along the Salmon River. The majority of the Hells Canyon Recreation Area and Wilderness, which was designated in 1975, is in Unit 18.

Land ownership in this DAW is approximately 80% publicly owned with the remaining 20% private. The privately owned portions are at lower elevations along the Clearwater and Salmon rivers. Approximately 10% of this DAW is Wilderness. Habitat productivity for bears is moderate in comparison to most other Clearwater Region big game units. The majority of this DAW is characterized by productive conifer forests with intermixed grasslands. Many forested areas have become overgrown with lodgepole pine and fir due to fire suppression during the past 40 years. Both open and closed road density is high within the DAW contributing to significant big game vulnerability during hunting season.

MANAGEMENT OBJECTIVES

DAU 1F will be managed to maintain the heavy harvest targets of <25% age 5+ bears in the male harvest and >40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1G

Game Management Units 19A, 23, 24, and 25

DESCRIPTION

Extra bear tags and liberal seasons were common in this DAU until the mid-1980s. More restrictive seasons and a one bear limit were implemented with the 1986-90 Black Bear Species Management Plan. Since then, bear harvest has been stable.

Approximately 70% of DAU 1G is in public ownership. Most land is managed by the USFS. Open, scattered shrub communities at lower elevations and mixed-conifer forests at mid to upper elevations characterize habitat. The wide valley bottoms of the upper Little Salmon River and North Fork Payette River are dominated by agri-business and housing developments. Bear habitat is considered good in this DAU.

High road densities exist in the western half of the DAU. Few roads (less than .25 mile per square mile) are found in the rest of the DAU. The Rapid River, Patrick Butte, French Creek, and Needles roadless areas occur in this area.

Livestock depredations and bear nuisance complaints are common in DAU 1G. Bear kills by Wildlife Services in response to sheep depredations average about 5 bears a year. Bear nuisance complaints are mostly related to poor garbage disposal practices and have been numerous during years with poor berry crops.

MANAGEMENT OBJECTIVES

DAU 1G will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1H

Game Management Units
22, 31, 32, and 32A

DESCRIPTION

High vulnerability of bears to hunting in this DAU has been a continual concern to sportsmen. Historically, baiting and hunting bears with the use of hounds have been restricted in DAU 1H. Bear seasons became increasingly more conservative with the implementation of each of the last three black bear species management plans. In 1993, general seasons were eliminated in favor of controlled hunts.

Approximately 60% of DAU 1H is not productive bear habitat, consisting of desert and irrigated agricultural lands. Over 90% of the bear habitat in this DAU is publicly owned and managed by the U.S. Forest Service. Road densities often exceed 3.0 miles per square mile. Bear habitat is characterized by open, scattered shrub communities at lower elevations and mixed-conifer forests and scattered onion beds and shrubfields at mid to upper elevations. Where present, bear habitat is considered excellent in this DAU.

Livestock depredations by bears are rare in this DAU, as cattle occupy most grazing allotments. Depredations on apiaries were infrequent in the past, but have been increasing recently as a result of apiary businesses expanding into bear habitat. Education of apiary owners and installation of electric fences is reducing this concern.

MANAGEMENT OBJECTIVES

DAU 1H will continue to be managed as a controlled hunt area because of the popularity of this area for bear hunting. Baiting and the use of hounds will continue to be restricted in this DAU. DAU 1H will be managed to maintain the light harvest targets of >35% age 5+ bears in the male harvest and <30% females in the total harvest.

METHOD OF TAKE

1993 - 1997

SEASON

1993 - 1997

DAU 1I

Game Management Units 34, 35, and 36

DESCRIPTION

These units contain almost continuous, good quality bear habitat; most of which is forested public land. Topography varies from large areas of flat to gently rolling terrain to the extremely rugged and rocky Sawtooth Mountains. Much of the area is lightly roaded or roadless; some is designated Wilderness, and the large Frank Church River of No Return Wilderness is adjacent to the north and east.

Over the past decade, DAU 1I has averaged about 33 bears harvested per year, or about 1.8 bears per 100 square miles. Relatively short spring seasons, limited road access, and distance to major human populations (2-3 hours driving time) have combined to produce a lightly harvested bear population. Age five and older bears consistently comprise over 40% of the male harvest, averaging 53% over the past decade. Similarly, females average 33% of the total harvest.

DAU 1I, particularly Unit 36, attracts considerable human recreational activity through most of the year. During the peak summer and early fall months, bear depredations are an almost constant concern at campgrounds and summer homes. Unit 36 also experiences an occasional bear attack on domestic sheep. Depredation problems multiply during dry summers when range forage cures early and/or when berry production is low.

MANAGEMENT OBJECTIVES

To address depredation concerns and to test the validity of bear harvest rate indicators. DAU 1I will be managed to meet the heavy harvest targets of <25% of the male harvest comprised of age 5+ bears and females comprising >40% of the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1J

Game Management Units
21, 21A, 28, and 36B

DESCRIPTION

The vegetation in DAU 1J varies from dry river breaks and sagebrush grasslands to subalpine, with most of the area in dry to moderately moist coniferous forests. Berry-producing habitats occur as isolated stringers along lower elevation riparian zones; where *Ribes* sp, serviceberry, chokecherry, and elderberry are common; or more generally widespread huckleberry stands at higher elevations in the north end of the DAU. Overall, the topography is steep and rugged, although more gently rolling terrain does exist in some areas. Access is somewhat limited, but varies from unroaded Wilderness to a few logged areas with high road densities. Bear densities are low to moderate, reflecting habitat capacity, and probably could not substantially increase.

Over the past decade, DAU 1J has averaged about 64 bears harvested per year, or about 2.4 bears per 100 square miles. Rugged terrain, limited access, and distance to major human populations (3+ hours driving time) tend to moderate bear harvest. Age five and older bears consistently comprise 35-45% of the male harvest, averaging 40% over the past decade. Similarly, females average 36% of the total harvest. During years with a dry summer and fall, bear harvest significantly increases as bears more actively forage for food in the fall, particularly along streamsides where roads and hunters often occur.

Depredations regularly occur in this DAU every year, typically involving campgrounds, garbage, pet food, beehives, and fruit orchards. Depredation problems multiply during dry summers when range forage cures early and/or when berry production is low.

MANAGEMENT OBJECTIVES

DAU 1J will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1K

Game Management Units
33, 39, and 43

DESCRIPTION

These units are made up of drainage that runs to the south and west. The topography is mainly ridges that run southwest. There is the south side mainly dry and covered with grass-shrub communities. The north sides are treed with conifers and have wetter communities. There are plant communities that have berry producers, there is not a constant supply since drought conditions significantly influence the production levels. All three units have areas that are highly roaded. They all have areas that can be considered reserve areas that hunters do not get into. The units are within easy distance of the Boise metropolitan area and the large number of hunters that are located there. In all units there are some level of depredations. They range from livestock depredations to campground raiders. Another major problem is the movement of bears into the urban areas such as Boise.

Over the past decade, DAU 1K has averaged 133 bears harvested per year. Seasons have gone from long with multiple bear tags to shorter seasons.

MANAGEMENT OBJECTIVES

DAU 1K will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 1L

Game Management Unit 6

DESCRIPTION

This DAU is a mix of private property, mainly timber company lands, with a mix of US Forest Service, Bureau of Land Management, and Idaho Department of Lands property. This area has been influenced heavily by logging and, to a lesser extent, by the large fires of the early 1900s.

Road densities range from moderate to high. Black bear densities are low, and baiting of black bears has not been allowed since 1983 because of low densities.

Total harvest in DAU 1L has averaged 54 bears from 1993 to 1997. Mature males (≥ 5 years old) make up 25% to 45% of the harvest and in 1997 the 3 year average was 31%. The harvest has increasingly been made up of females and the percent of mature females in the harvest is fairly high. Harvest statistics indicate a fairly heavily hunted population.

MANAGEMENT OBJECTIVES

DAU 1L will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 2A

Game Management Units 10 and 12

DESCRIPTION

Until the 1930s, wildfires were the primary habitat disturbance mechanism in this DAU. Between 1900 and 1934, approximately 70% of the Lochsa River drainage was burned by wildfires creating a diversity of habitat and shrub species. Between 1926 and 1990, over 1,900 km of roads were built in this area to access marketable timber. State Highway 12 along the Lochsa River was completed in 1962 and became the primary travel corridor. In 1964, most of the southern portion of Unit 12 was designated as part of the Selway-Bitterroot Wilderness.

Land ownership within this DAU is almost entirely publicly owned forest. The southern portion of the DAU is within the Selway-Bitterroot Wilderness Area. Historically, habitat productivity was high in this DAU and remains so in the western portion due mainly to publicly logged forest creating early successional forest with intermixed brush. The remaining portion of the unit has decreased in habitat productivity mainly due to fire suppression. Approximately one-third of the DAU has good access for motorized vehicles with medium road densities. The remaining portion has low road densities with good trails contributing to medium to low big game vulnerability.

The warm maritime climate provides the most productive bear habitat in the Clearwater Region. High precipitation levels, dense forests, and roadless areas allow for relatively dense bear populations.

MANAGEMENT OBJECTIVES

DAU 2A will be managed to maintain the heavy harvest targets of <25% age 5+ bears in the male harvest and >40% females in the total harvest.

TOTAL HARVEST

METHOD OF TAKE

1993 - 1997

SEASON

1993 - 1997

DAU 2B

Game Management Units 7 and 9

DESCRIPTION

This DAU is the most remote from human population centers of any DAU in the Panhandle Region. In addition, persistent snowdrifts make spring travel difficult, and substantial roadless areas preclude high levels of use. The US Forest Service manages most of the habitat in this DAU.

Total harvest in DAU 2B has averaged 41 bears from 1993 to 1997. Mature males (≥ 5 years old) make up nearly 40% of the population but have shown a decline in the past 5 years. However, small sample sizes in this DAU can lead to variable results. Females make up a small percent of the harvest and mature females do not appear to be heavily harvested. Harvest statistics indicate a light to moderate harvest level in this DAU.

MANAGEMENT OBJECTIVE

DAU 2B will be managed to increase harvest to the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 3A

Game Management Units 16A, 17, 19, and 20

DESCRIPTION

Due to the rugged and remote nature of this DAU, human impacts have been very limited. In 1964, almost all of Unit 17 and a small portion of Unit 16A were included in the Selway-Bitterroot Wilderness. Most of Unit 19 became part of the Gospel Hump Wilderness in 1978, and in 1980, part of Unit 20 was included in the Frank Church River of No Return Wilderness.

Habitat productivity varies throughout the DAU from high precipitation forested areas along the Lower Selway River to dry, steep, south-facing ponderosa pine and grassland habitat along the Salmon River. High elevation habitats in the southern portion are dominated by Whitebark Pine, an important bear food. Many areas along the Salmon River have a good mix of successional stages due to frequent fires within the Wilderness. Fire suppression within portions of the Selway River drainage has led to decreasing forage production for big game. Road densities are low, contributing to low vulnerability for big game. Large proportions of hunters in this DAU are nonresident.

MANAGEMENT OBJECTIVES

DAU 3A will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

SEASON 1993 - 1997

DAU 3B

Game Management Units 20A, 26, and 27

DESCRIPTION

Extra bear tags and liberal seasons were common in this DAU until the mid-1980s. More restrictive seasons and a one bear limit were implemented with the 1986-90 Black Bear Species Management Plan. Season lengths still remain the most liberal in Idaho. Bear harvest has been light, dominated by young, dispersing bears or occasional older bears, and occurs mostly along river corridors and backcountry landing strips.

Most of DAU 3B is in public ownership, roadless, and lying within wilderness boundaries. Except for a few mining roads penetrating the periphery, access in these units is restricted to airplane, packstring, or foot travel. The steep canyon breaks of the Middle Fork Salmon and main Salmon rivers characterize the lower elevations of this DAU. Mid to upper elevations are dominated by mixed conifer forests. Bear habitat is of moderate productivity in this area.

Livestock depredations and human/bear conflicts generally do not occur in this DAU.

MANAGEMENT OBJECTIVES

DAU 3B will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

SEASON 1993 - 1997

DAU 4A

Game Management Units 44, 45, 48, and 49

DESCRIPTION

Units comprising DAU 4A are located in the Magic Valley Region in south central Idaho, north of the Snake River. The population centers of Boise, Twin Falls, Sun Valley-Ketchum and Burley are within 100 miles of this area. Elevations range from 2,800 feet in the Bennett Mountains (Unit 45) to over 12,000 feet in the Pioneer Mountains (Unit 49).

The area has moderately long, cold winters and hot, dry summers. Annual precipitation ranges from 10 inches in the lower elevations to 32 inches in the higher elevations and occurs primarily as snow from November to February.

At lower elevations, vegetative communities are composed mostly of sagebrush, aspen, hawthorn, and chokecherry in riparian areas, and some sparse stands of Douglas fir. Middle and high elevation areas are characterized by open, mountain sagebrush on south and west slopes, and ponderosa pine and Douglas fir on north and east slopes. Berry-producing plants are very limited throughout area.

Major land uses affecting this DAU are livestock grazing and year-round recreational activities. Logging was a predominate use in the 1960s and 1970s but is uncommon now because most merchantable timber has been removed. Access throughout most of the DAU is good, except the upper Little Wood River drainage, which is roadless.

MANAGEMENT OBJECTIVES

DAU 4A will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

1993 - 1997

SEASON

1993 - 1997

DAU 4B

Game Management Units
50, 51, 58, 59, and 59A

DESCRIPTION

Data Analysis in Unit 4B is comprised of Big Game Management Units 50, 51, 58, 59, and 59A in eastern/east central Idaho. These mountain and valley units are bisected by the Pioneer, White Knob, Lost River, Lemhi, and Beaverhead mountain ranges.

Elevations range from 4,824' at Howe to 12,662' on Mount Borah. The higher elevations are glacial cirque basins and lakes are surrounded by rocky mountain peaks. These peaks give way to alpine basins, flats and benches, and finally more gently sloping hills at lower elevations. Numerous canyons with steep, rocky slopes dissect these mountain ranges.

DAU 4B contains relatively dry bear habitats where timber stands are generally distributed on moister north and east aspects. The majority of this timber is over-mature Douglas fir and lodgepole pine scattered within a sagebrush/grass community. Engelmann spruce and subalpine fir are the most abundant of the secondary species, in addition to quaking aspen, mountain mahogany and some whitebark pine. Wet sedge meadows are common in some portions of the DAU. These habitats are marginal for black bear because they grow few berry-producing shrubs.

Approximately 85 percent of the DAU is publicly owned. Most of the bear habitat occurs on lands administered by the US Forest Service. Some lower elevation habitat occurs on BLM and privately owned lands. Both cattle and sheep allotments occur throughout the area.

There is a sparse human population living within the DAU, and the area receives fairly heavy recreational use on a year-around basis. However, the relatively long distance to major population centers probably keeps bear hunting activity at low to moderate levels.

Although much of the topography in the DAU is rugged and largely unroaded, concern has developed regarding ever increasing ORV use throughout all management units.

MANAGEMENT OBJECTIVES

Maintain harvest levels consistent with the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

TOTAL HARVEST

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

DAU 4C

Game Management Units 60, 61, 62, and 62A

DESCRIPTION

Data Analysis Unit 4C consists of Big Game Management Units 60, 61, 62, and 62A in eastern Idaho. The most prominent geographical features in DAU 4C include the Centennial Mountain Range, the Island Park Caldera, and the Fall River Ridge. Elevations range from below 5,000' in the southwestern portion of the DAU to many peaks in the 9,000-10,000' range along the Idaho-Montana border.

A large percentage of the black bear habitat in DAU 4C occurs on public land administered by the US Forest Service. DAU 4C contains relatively dry bear habitats that grow few berry-producing plants. Lodgepole pine and Douglas fir communities are common in lower elevation sites. Spruce and subalpine fir communities are prevalent along drainage bottoms. Subalpine fir and whitebark pine communities occur at higher elevations.

DAU 4C has an extensive network of roads and clearcuts throughout the eastern portion of the DAU. Recent implementation of road and area closures in some areas should help to offset some of these affects in the future.

The livestock industry is a major resource user in DAU 4C. Both sheep and cattle allotments occur in the area.

There is a sparse human population living within the DAU on a permanent basis. However, cabins and summer homes are plentiful on the private inholdings in the Island Park area and tourist traffic is heavy. The DAU is readily accessible from the nearest population centers of Rexburg, Idaho Falls, Blackfoot, and Pocatello. However, the distances from population centers keeps bear hunting activity at relatively low to moderate levels.

MANAGEMENT OBJECTIVES

Management options are somewhat limited in DAU 4C due to the existence of an established grizzly bear population in the Greater Yellowstone Ecosystem. This area will continue to be managed to protect this threatened grizzly population by prohibiting baiting and the use of hounds to hunt black bear. Maintain harvest levels consistent with the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

SEASON

1993 - 1997

DAU 4D

**Game Management Units
64, 65, 66, 66A, 67, 69, and 76**

DESCRIPTION

Data Analysis Unit 4D is comprised of Big Game Management Units 64, 65, 66, 66A, 67, 69, and 76 on the Targhee and Caribou National Forests in eastern and southeastern Idaho.

Elevations range from approximately 4,500' at Blackfoot to 10,025' on Mt. Baird in the Snake River Range. The Big Hole Mountains and Snake River Range comprise the northern portion of the DAU. The Big Holes are characterized by steep mountains, rocky slopes, and lush subalpine meadows. The Snake River Range consists of high elevation alpine glaciated mountain peaks, cirques, talus slopes and moraines that connect through numerous steep, parallel canyons, ridges and slopes. The foothills consist of glacial outwash terraces and extensive areas of colluvial deposition. Vegetation varies with elevation and exposure. Scattered stands of subalpine fir, Engelmann spruce and timber pine are interspersed through the alpine meadows in the higher elevations. Intermediate elevations contain grasses, forbs, low growing shrubs and aspen on south and west exposures while dense stands of aspen, spruce, Douglas fir, and lodgepole pine grow on north and east aspects. Lower elevations consist of sagebrush/grass communities. The Caribou Range comprises the southern portion of the DAU. Major vegetation cover types consist of lodgepole pine, Douglas fir, aspen, mountain brush, and sagebrush/grass. DAU 4D provides only marginal bear habitat because it is relatively dry and grows few berry producing plants.

Most of the bear habitat in DAU 4D is found on public land administered by the US Forest Service. Some lower elevation habitat occurs on BLM and privately owned lands. Both cattle and sheep allotments occur throughout the area.

A relatively large human population resides in and immediately adjacent to DAU 4D. Major population centers include Rexburg, Idaho Falls, Blackfoot and Pocatello. The area is characterized by plentiful road access. The combination of easy access and proximity to human population centers results in at least moderate bear hunting activity levels, especially in the northern portion of the DAU.

MANAGEMENT OBJECTIVES

Maintain harvest levels consistent with the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

SEASON 1993 - 1997

DAU 4E

Game Management Units
29, 30, 30A, 36A, 37, and 37A

DESCRIPTION

DAU 4E is in general a low precipitation zone with broad, treeless valleys and scattered pockets of bear habitat in the mountains. Much of the DAU is in marginal sagebrush-grassland habitats or agricultural ground. Good quality bear habitat is limited. Consequently, bear populations tend to be low density and isolated. Although the highest elevations in the mountains are extremely rugged and rocky (too much so to be good bear habitat), much of the area is flat to moderately rugged. Most canyon bottoms are roaded, and much of the rest of the relatively gentle topography is accessible to all-terrain vehicles.

Over the past decade, DAU 4E has averaged about 30 bears harvested per year, or about 0.9 bears per 100 square miles. Although moderately distant from major human populations (2-3 hours of driving time), bear populations in these units can be vulnerable to over-harvest because of the limited, isolated habitats and relative ease of motorized access. However, age five and older bears consistently comprise 30-40% of the male harvest, averaging 36% over the past decade. Similarly, females average 35% of the total harvest

Depredations occasionally occur in this DAU, typically involving campgrounds or beehives. Depredation problems multiply during dry summers when range forage cures early and/or when berry production is low.

MANAGEMENT OBJECTIVES

DAU 4E will be managed to maintain the moderate harvest targets of 25-35% age 5+ bears in the male harvest and 30-40% females in the total harvest.

METHOD OF TAKE 1993 - 1997

SEASON 1993 - 1997

APPENDIX I

GUIDELINES FOR HANDLING BLACK BEAR - HUMAN CONFLICTS:

The Department recognizes that black bears occasionally damage private property, prey on domestic livestock, and jeopardize public safety. The improper storage of human foods and garbage is often the primary factor leading to bear-human conflicts. Other factors include inadequate supplies of natural foods, injuries, and, in the case of sub-adult bears, inexperience in locating natural foods. Human encroachment into black bear habitat is a major cause of many depredation problems. The purpose of this section is to establish guidelines for minimizing damage to private real property and livestock, reducing the potential for public safety concerns regarding black bears, and to provide guidance to Department employees on how to handle situations in which black bears become nuisance or public safety problems.

Areas of Responsibility:

By Memorandum of Understanding, the Department (IDFG) and the U. S. Department of Agriculture's Wildlife Services Program have agreed to share the responsibility for handling depredation situations using the following guidelines:

1. IDFG has the responsibility for controlling black bears in nuisance and human safety situations. Wildlife Services may handle these complaints at the request of IDFG if mutually agreed upon by both parties.
2. Wildlife Services has the responsibility for controlling black bears that commit livestock (including apiaries) depredation problems. IDFG may handle these complaints at the request of Wildlife Services, if mutually agreed upon by both parties.
3. Wildlife Services has the responsibility to investigate all black bear depredation payment claims involving domestic sheep, cattle, apiaries, and berries.
4. In areas where public safety is a concern and in non-livestock agricultural complaints, Wildlife Services and IDFG will use non-lethal methods, preferably culvert traps or trailing dogs, whenever practical.
5. IDFG and Wildlife Services will use culvert traps in classified grizzly bear habitat unless determined to be impractical. Snares used in classified grizzly bear habitat must be sufficient to hold any grizzly bear caught.
6. Any black bear killed in a depredation situation by IDFG or Wildlife Services must be reported to an IDFG Regional office within 14 days of the date of the kill. The skull and a completed Big Game Mortality Report form must be submitted to the Department. All salvageable parts remain the property of the Department and must be submitted to the Regional Office for disposal. Where practical, the meat from any black bear killed in a depredation situation should be salvaged and handled according to Policy E-24.00 in the Department's policy manual.

7. The Regional Supervisor is responsible for assigning personnel to handle black bear depredations and to ensure that they are properly trained and equipped, including training in the use of appropriate immobilization drugs. The responsible employee has the ultimate responsibility for deciding how to handle each depredation situation.

Response and Reporting Requirements:

1. IDFG regional personnel will respond to all reported black bear depredation incidents **within 24 hours**, either by phone or in person. The type and level of response will depend upon the nature of the complaint. Incidents involving human safety or significant property damage will receive high priority and the personal attention of the responsible employee. Those incidents involving low risk situations may be handled by phone, if an obvious solution is available.
2. The responsible employee, under authority of the Regional Supervisor, will verify the validity of each complaint, determine the appropriate action, and, if necessary, initiate control actions.
3. The responsible employee should provide the complainant with specific recommendations on how to prevent depredation problems, document any actions taken, and convey to the complainant that they may be held liable if someone is injured or incurs damage as a result of their providing attractants to nuisance bears.
4. Within seven (7) days of the conclusion of the problem, a report, using form D-3, will be submitted to the Regional Landowner Sportsman Coordinator or Regional Wildlife Manager by the person handling each depredation complaint.

Response Categories and Remedial Actions:

The **prevention** of black bear depredations is the primary goal of these guidelines. To that end, Department personnel are encouraged to work with state and federal land management agencies and the public to eliminate attractants for bears. In situations where chronic bear depredation problems are occurring, Department personnel should be prepared to recommend permanent solutions that will eliminate the attractants.

Category 1 Situations: These situations involve black bears that have caused minimal or no damage and appear to be first time offenders. These situations are characterized by bears involved in **nocturnal** visits around occupied homes to feed in garbage cans or dumpsters, eating pet foods (or the pets themselves), or climbing domestic fruit trees in or adjacent to good habitat or travel corridors. In these situations, attractants should be removed or secured by the landowner (picking fruit and feeding pets indoors) and the bear allowed to resume its natural feeding habits. Hazing and other non-lethal techniques (using hounds, etc.) are appropriate methods to use on bears in these situations. If the bear is located in an area that is not suitable habitat, the bear should be removed from the area using appropriate capture methods and released in suitable habitat.

Category 2 Situations: These situations involve black bears that have become conditioned to human foods or habituated to humans and are nuisance problems. These bears are often involved in repeated **nocturnal** incidents involving garbage cans and dumpsters, feeding on dog or horse food near residences, disturbing campsites, or damaging commercial fruit trees or apiaries. Black bears that have been previously captured and have returned to areas of human habitation are included in this category. **In these situations, increased emphasis should be placed on eliminating attractants from the area.**

Category 2 bears should be trapped, ear-tagged (when practical), removed from the area, and released in areas where they are not expected to return to the original capture site.

Category 3 Situations: These situations involve black bears that have caused significant real property damage to a dwelling, structure, vehicle, are a threat to human safety (the bear is demonstrating aggressive behavior towards humans, is showing little fear of humans, or is causing depredation problems during daylight hours), or are chronic offenders (involved in 3 or more depredation situations). Corrective action in these situations requires that the offending animal be destroyed (euthanized) using the most expedient means. The Regional Supervisor or immediate supervisor should be consulted and concur with the recommendation to destroy any problem bears.

Category 4 Situations: These situations involve black bears that meet the criteria described in Category 3, but involve unique circumstances where the use of culvert traps and snares is not practical or has been ineffective. In these situations, Depredation Kill Permits may be issued to private landowners to assist the Department in solving a depredation problem. In all instances, the Regional Supervisor or his/her designee shall inspect the site prior to issuing the permit to insure there are no obvious human safety concerns in issuing the permit. Depredation Kill permits shall be issued only during the closed season for black bear and should not be issued to landowners if they cannot be safely administered. Depredation Kill permits should not be issued in situations involving female bears accompanied by young. These situations should be handled by trapping and removing the offending animals. If circumstances require the female to be euthanized, the cubs should be taken to a rehabilitation facility and released when their body condition is good and sufficient natural foods are available or, dened in a natural or artificial den. Black bears killed under Depredation Kill Permits remain the property of the state.

GUIDELINES FOR TRAPPING, HANDLING AND RELEASING DEPREDATING BEARS:

1. Only IDFG personnel are authorized to capture and relocate nuisance black bears, except that Wildlife Services personnel may capture bears involved in livestock depredations (including apiaries) as indicated in the MOD between IDFG and Wildlife Services.
2. Any black bear that is trapped and handled by IDFG in a depredation situation should be ear-tagged or otherwise marked (i.e. paint) prior to release.
3. All black bears captured and immobilized during or less than 2 days before an open bear season should be held in a culvert trap or other suitable facility for 24 hours before being released to allow the animal to metabolize any residual drugs from its system. Black bears should be held in captivity in a secure area with adequate water. The person responsible for trapping or caring for the bear should provide shelter from extremes in weather. Biologists using Capture all-5 or Ketamine hydrochloride, alone or in conjunction with a tranquilizer to immobilize captured bears, should administer Yohimbine hydrochloride (antaganil) to reverse the effects of the tranquilizer on the animal.
4. Culvert traps and snares set for black bear should be checked by the person that is responsible for handling the complaint or his/her designee prior to 1000 hours each day the trap is set. Drop-door culvert traps and snares should not be left unattended or set in or adjacent to campgrounds or private residences if there is any concern for human safety in the area.
5. Snares should be anchored to fixed objects (live trees) using a car hood spring or tire (with back-up safety configuration) to minimize the potential for injury to the bear during the period between capture and immobilization.
6. Adequate signs should be posted around all culvert traps and snares to warn people that nuisance bears are in the area and that traps have been set to capture these animals. These signs should be posted near the trap sites and along trails and roads entering the area.
7. As a guideline, black bears should be released not less than 30 (sub-adults) to 50 airline miles (adults) from the capture site in suitable habitat.
8. Release sites for captured nuisance black bears should be selected in advance and must be coordinated with the appropriate land management agency (Idaho Code 36-1109a) and be approved by the Regional Supervisor.
9. To address potential human safety concerns, Department employees are encouraged to request that land management agencies close or restrict the use of campgrounds where nuisance black bears are active until the source of the problem (attractant) has been removed and the offending bear has moved on or is trapped.
10. Black bears that are captured in depredation situations that have serious injuries or disease conditions should be euthanized in a humane manner rather than released.
11. Orphaned cubs of the year should be placed in an approved rehabilitation facility. These cubs should be released only when their body condition has improved to the

point where they have a reasonable probability of surviving on their own and natural food supplies are abundant. If natural foods are scarce, black bear cubs should be retained in a rehabilitation facility until they can be placed in a natural or artificial den or until adequate spring foods are available.

12. Any black bear that has bitten a person will be euthanized and tested for exposure to rabies. Any bear that has injured a person will be euthanized in a humane manner.
13. Black bears involved in killing livestock will be killed in a humane manner. If the offending animal is a female accompanied by young of the year, the young should be captured and relocated or turned over to a wildlife rehabilitator, if it is unlikely that they would survive on their own.

APPENDIX II

BAITING STANDARDS

The following standards are recommended for implementation in this planning period.

1. Timing of the baiting season:
 - a. No baits may be placed for the purposes of attracting or taking black bear prior to the opening of the black bear take season.
 - b. All structures, bait containers and materials must be removed and excavations refilled when the site is abandoned or within seven (7) days of the close of the black bear take season.
2. Location of bait sites:
 - a. No bait site may be located within 200 yards of any free water (lake, pond, reservoir, spring, and stream); maintained trail; or any road.
 - b. No bait site may be located within one mile of any designated campground or picnic area, administrative site, or dwelling.
3. Types of bait:
 - a. No parts of or whole game animals, game birds, or game fish may be used to attract black bear.
 - b. The skin must be removed from any mammal parts or carcasses used as bait.
4. Bait containers:
 - a. No bait may be contained within paper, plastic, metal, wood, or other non-biodegradable materials, except that a single, metal container with a maximum size of 55 gallons may be used if securely attached at the bait site.
 - b. Baits may be contained in excavated holes if the diameter of the hole does not exceed 4 feet.
5. Establishment of bait sites:
 - a. Any structures constructed at bait sites using nails, spikes, ropes, screws, or other materials must be removed when the site is abandoned by the permit holder or within seven (7) days of the close of the black bear take season.
 - b. All bait sites must be visibly marked at the nearest tree or on the bait container using a tag supplied by the Department.

6. Baiting permit administration:

- a. All persons placing or hunting over bait must possess a baiting permit issued by the Idaho Department of Fish and Game.
- b. Each hunter (except licensed guides and clients of outfitters) may possess only one Idaho Department of Fish and Game baiting permit each year and may maintain up to three (3) bait sites.
- c. No person may hunt over an unlawful bait site.
- d. Limits on the number of bait sites that can be established by outfitters operating on public lands must be specified in their operating plans. Licensed outfitters operating on private lands must have a letter authorizing a specified number of bait sites from the owner of those lands.
- e. Guides and clients of outfitters are not required to obtain a baiting permit, but they must have a copy of the outfitter's permit in their possession while hunting over a bait site.
- f. Baiting permits will be issued by mail or in person at Idaho Department of Fish and Game regional and sub-regional offices beginning March 1 each year.
- g. Permits will be valid for the calendar year in which they were issued.
- h. Possession of an Idaho Department of Fish and Game baiting permit does not exempt the permit holder from any restrictions placed on users of federal, state, or private lands.

MOUNTAIN LION CONSERVATION AND MANAGEMENT GUIDELINES

With the publication of this document, Montana Fish, Wildlife & Parks (FWP) reaffirms its commitment, on behalf of the public, to the conservation and responsible management of mountain lion populations in Montana.

Many FWP wildlife biologists might find it redundant to first state that we are committed to conserving mountain lions. We tend to skip instead to describing specific strategies for mountain lion management, while taking our professional dedication to wildlife conservation for granted.

But we've learned over the years that an intensely interested and engaged public does not always accept FWP's commitment to mountain lion conservation as a given, and may not recognize FWP's management strategies as being consistent with conservation. Although our society has a long and evolving heritage of valuing wildlife, we

acknowledge that Montana and other western states have risen relatively recently to the challenge of actively conserving mountain lions.

Many Montanans can still remember the bounty years when antagonistic public attitudes toward predatory wildlife were common. Since then, questions and concerns surrounding the management of mountain lions have increased as more people with a stake in mountain lion management come to the table.

One measure of Montana's commitment to wildlife conservation is the abundance, diversity, and distribution of our large predators. Wolves are now biologically and legally recovered, grizzly bear populations exceed restoration milestones, and the mountain lion has re-occupied its historic statewide habitat.

But with this success comes increased management complexity. Local declines in elk abundance and hunting opportunities, concerns about public safety, sharply responsive mountain lion hunting regulations, and uncertainties about management's effects on lion populations have sometimes strained a consensus about our values and management direction.

And conservation itself, we understand, is in the eye of the beholder. So, we strive to be clear. The following are the conservation and management guidelines that will direct FWP's decisions, and against which more specific management objectives will be measured.

FWP will conserve mountain lions as a functional and valued part of Montana's wildland ecosystems.

FWP will help manage suitable and connected habitat at a landscape scale for mountain lions and their prey.

FWP will responsibly manage mountain lions as a public trust resource and consistent with state law.

FWP will maintain and enhance public acceptance of mountain lions by helping landowners, homeowners, and the recreating public prevent conflicts with mountain lions. FWP will respond promptly and professionally when conflicts occur.

FWP will enhance public appreciation for mountain lions by providing information and insight about the role of mountain lions in the ecosystem and on practices for living and recreating in lion habitat.

FWP recognizes that mountain lion hunting is a highly valued recreational pursuit and that hunting plays a critical role in maintaining public advocacy and tolerance for the species. FWP will therefore manage for limited and sustainable mountain lion hunter-harvest opportunity on most lands within its jurisdiction. FWP will allocate hunting opportunities and experiences fairly among Montana resident, nonresident, and outfitted mountain lion hunters using simple and consistent regulations.

FWP will use an adaptive harvest management framework to develop and evaluate most mountain lion management decisions. Potential management objectives will be made explicit to all stakeholders throughout the decision-making process and the best available information will be used to evaluate whether those objectives are being met.

FWP will maintain a balance between mountain lion populations, their prey, and humans by directing local harvest of mountain lions, if and as needed, to manage prey survival and reduce human-lion conflicts. FWP specifically recognizes that mountain lion populations are most effectively conserved at the landscape scale, rather than within smaller individual Lion Management Units where prey survival or points of conflict may be concerns worthy of management.

FWP will develop informed public consent regarding the conservation status of mountain lions and the potential consequences of FWP management actions by instituting a credible, science-based system for estimating and monitoring Montana's lion populations.

FWP will consider, monitor, and conserve mountain lions at a landscape scale, consistent with the species' ecology. Specific management objectives will encourage sustainable and well-connected mountain lion populations within these landscapes.

EXECUTIVE SUMMARY

Despite historic persecution, mountain lions are thriving once again in Montana. Lions have reoccupied their historic statewide range and dispersing individuals now contribute to expanding populations across the western and midwestern U. S. This recovery is a testament to Montana's tradition of protecting habitat, conserving native wildlife populations, and investing in research that provides the scientific basis for sound wildlife management decisions.

The number of lion hunters and hound handlers has also increased during the last 40 years. These sportsmen and women became the state's most effective advocates for lion conservation and they have consistently encouraged FWP's efforts to improve lion management. Montanans, hunters and non-hunters alike, now expect assurances from FWP that lion populations remain healthy and that lion

management decisions are informed by objective data instead of emotion.

Unfortunately, many past lion management decisions were controversial. Because it was impossible to precisely count lions or monitor population trends, Montanans who care deeply about lions and their prey often disagreed about the effects of lion harvest on both.

FWP clearly realized the need for better methods to track lion population changes and for a scientific framework upon which to base management recommendations. Over the last 25 years FWP made significant investments in field research that had improved our understanding of lion ecology and the way lions interact with their prey. FWP biologists and partners also developed new methods to monitor lion populations and built innovative population models that predict the effect of past and future harvest.

FWP intends to maintain sustainable lion populations across all suitable habitats within its jurisdiction. An important goal of this Strategy is to provide the public

West Fork Bitterroot River FWP Mountain Lion Study Area

and the Department with accurate and timely information so that both populations and harvest are more stable over time. Accurate monitoring and modeling data will enable simpler harvest regulations, improve our ability to reduce conflicts, and allow FWP to better manage local lion densities while protecting regional populations.

Research in Montana and other states has revealed that lion ecology is remarkably similar across the species' western North American range. Populations in western North America are well connected and generally resilient to moderate harvest. However, hunter harvest is often additive to other forms of mortality and should be limited to prevent unwanted population declines. Critically, we now understand that lion populations are most effectively managed at large spatial scales.

For this management strategy FWP used a habitat model, built using Montana-based research and harvest data, to describe four biologically meaningful mountain lion "ecoregions" within the state. These ecoregions will be the spatial basis of FWP's lion management. FWP will periodically develop estimates of mountain lion abundance within most ecoregions using genetically-based field sampling.

Managers will then include these population estimates, our understanding of lion ecology, and lion harvest data to inform statistical models that predict the effects of lion harvest on statewide populations. Over time, this monitoring program will reduce uncertainty about the effects of lion harvest and will improve FWP's ability to meet lion management objectives.

An adaptive harvest management process will guide most of Montana's mountain lion harvest decisions. FWP will work with the public to develop clear and measurable population objectives at the ecoregion scale, as well as hunting seasons and harvest prescriptions that are most likely to meet those objectives. The effects of lion harvest will be regularly monitored so that harvest can be adjusted based on current information.

Although overall management objectives and harvest prescriptions will be developed at a large (ecoregional)

scale, harvest limits will generally be distributed across an ecoregion's lion management units to address social concerns, reduce hunter crowding, and focus or limit harvest where needed.

The following chapters describe FWP's mountain lion monitoring program and methods to produce periodic estimates of mountain lion abundance across the state. This Strategy includes a population model that will allow managers to effectively use those field-based estimates and other information to make predictions about the effect of future mountain lion harvest. We present policies detailing how FWP will reduce and respond to human-lion conflicts. Finally, we describe an adaptive harvest management process that will help FWP and the public build realistic lion management objectives and how to evaluate whether those objectives are being met.

This Management Strategy represents FWP's long term commitment to use the best available scientific information to ensure that mountain lion management decisions are as objective, transparent, and adaptive as possible.

ACKNOWLEDGEMENTS

This document is a synthesis, and practical application, of fundamental mountain lion field research conducted over decades in western North America. We sincerely thank the many wildlife biologists, technicians, and managers whose efforts have contributed to our understanding of lion ecology. Their body of work specifically informed this effort and will help ensure the continued conservation of mountain lions in Montana.

Several biologists made specific and fundamental contributions to this strategy. Dr. Hugh Robinson of Panthera guided important Montana lion field research to publication and built lion habitat models that became critical components of this strategy.

Dr. Josh Nowak and Dr. Paul Lukacs, both with the University of Montana, worked with FWP to construct an interactive model that describes how harvest affects mountain lion populations. This model, and the web-based interface they built, will allow FWP to make better lion management decisions going forward.

FWP research scientist Dr. Kelly Proffitt developed innovative field and statistical methods to estimate local lion abundance and to extrapolate those estimates more broadly. Dr. Proffitt's work, and good advice, made this strategy possible.

FWP Game Management Bureau Chief John Vore patiently guided this strategy from its inception. His council and critical reviews vastly improved this document.

Justin Gude, FWP's Wildlife Research Chief, effectively advocated for and helped implement many of the projects that developed core components of this strategy. It would not have been possible without his vision and support.

FWP's Mike Thompson helped make clear that this strategy is intended to conserve Montana's mountain lions, not simply manage them. We sincerely appreciate both his perspective and eloquence.

Many FWP biologists and managers reviewed earlier drafts of this strategy and it was much improved by those efforts. Julie Cunningham, Adam Grove, Jessy Coltrane, Heather Harris, Elizabeth Bradley, Howard Burt, Ben Jimenez, James Jonkel, Jay Newell, Scott Eggeman, Justin Gude, Kelly Proffitt, Nick DeCesare, and Brent Lonner contributed and/or compiled particularly thorough and valuable comment.

Members of the Montana State Houndsmen Association, Northwest Houndsmen Association, Ravalli Co. Fish and Wildlife Association, unaffiliated hound handlers, and others with a stake in lion management provided important input during the development of this draft. Their continued engagement as the strategy is finalized and implemented will be critical.

Mountain lion hunting in snow, D. Neils

CHAPTER 1

MOUNTAIN LIONS IN MONTANA

Mountain lions were historically found in most of Montana except on its open plains and prairies (Young & Goldman 1946). Like other predators, Montana mountain lions had a bounty placed on them from 1879 to 1962. The number of bounties paid declined from a high of 177 in 1908 (at \$8) to fewer than 5 per year by 1925 (at \$25; \$350 in 2016 dollars). At least 1,562 lion bounties were paid between 1900 and 1930 (Riley 1998). Mountain lions were nearly extirpated from the state by 1930 due to widespread persecution and the severe depletion of their ungulate prey.

Mountain lions began to recover in core Montana habitats during the 1950s as deer and elk numbers increased. Lions were designated as a predator from 1963 until 1971 when the state legislature reclassified the species as a game animal and transferred their management to the Fish and Game Commission.

Martin Bright and Ed Lord, Bitterroot Valley, 1890.

Lions expanded their range, and legal harvest increased, over the next 20 years (Figure 1, Table 1). In western Montana during the mid- to late-1990s the number of public lion sightings grew, human-lion conflicts became increasingly common, and harvest quotas filled quickly.

After the severe winter of 1996-97 caused white-tailed deer herds in west-central and northwest Montana to decline by as much as 50% (Montana Fish, Wildlife and Parks 2006), human-lion conflicts (including several nonfatal attacks)

¹ Statewide totals differ from the Regions' sum because some harvest was reported as "unknown Region"

spiked. Managers were pressed to maintain historically high lion quotas in FWP Regions 1 and 2 because of concerns about public safety and to aid struggling prey populations. Lion harvest also reached record high levels during the late 1990s in Fish, Wildlife & Parks (FWP) Regions 3, 4, and 5.

By the early 2000s, many hound handlers believed that lion densities had significantly declined—an observation supported by ongoing FWP research in the Garnet Mountains. In response, the Fish and Wildlife Commission restricted the harvest of female lions during that decade in much of the state. By 2006, the Garnet Mountains research population had recovered to near 1990s densities (Robinson et al. 2014). Lions became increasingly common in eastern Montana FWP Regions 6 and 7 during the same period.

Mountain lions are now present in all suitable Montana habitats and continue to reoccupy neighboring states to the east. Between 1990 – 2016, an average of 450 lions were taken by licensed Montana hunters each year. Lions have been legally harvested in 49 of the state's 56 counties (Figure 2).

Harvest can be the most important factor affecting population size and growth where harvest occurs

Montana likely includes some of the most productive mountain lion habitat in North America. Although directly comparing lion densities across research projects and study areas is complicated (because of differences in field methods, inclusion of different sex-age classes in estimates, and the use of different areas over which density is calculated), reported North American lion densities generally range from 1 to 4 lions per 100 km² (37 mile²; Hornocker & Negri 2009). In western Montana, researchers using DNA based detection methods have recently documented mountain lion densities exceeding 5 lions per 100 km² (Russell et al. 2012, Robinson et al. 2014, Proffitt et al. 2015).

GENETIC CONNECTIVITY

Mountain lion populations across the central Rocky Mountain west are genetically well connected. When wildlife populations are small and isolated, individuals can become more genetically similar over time. Although male lions are more frequent long-range dispersers (Logan & Sweanor 2001), Biek et al. (2006a) found that in Montana and Wyoming, neither male nor female resident lions shared more genes than expected by chance. Thus, frequent introduction of new genes by immigrating males is likely sufficient to maintain genetic diversity in females despite their lower dispersal rates and distances (Goudet et al. 2002).

Similarly, Anderson et al. (2004) found that there is ample gene flow between mountain lion populations in Wyoming and Colorado despite their being separated by large areas of relatively poor habitat. Even small and geographically isolated lion populations in North and South Dakota have maintained genetic diversity over time (Juarez et al. 2016).

In Montana, researchers genetically analyzed the fast-evolving feline immunodeficiency virus that commonly infects wild mountain lions. Although the study's 352 samples were collected as far as 1,000 km apart, there was no evidence of genetic sub-structuring, genetic drift, or barriers to gene flow within Montana populations (Biek et al. 2006b).

MOUNTAIN LION DISEASE, PARASITES, AND HUMAN HEALTH RISK

Mountain lions carry few communicable diseases that potentially threaten humans but certain precautions should still be taken when handling both live animals and carcasses. Fifty-four percent of lions sampled in Montana between 1971 and 1989 tested positive for the *Trichinella* roundworm. All harvested lions should be treated as if they are infected because a negative lab test does not mean *Trichinella* is not present. This parasite is transmissible to humans and pets if they consume undercooked infected mountain lion meat. Although mountain lion hunters are not required by Montana law to retain a harvested lion's meat (MCA 87-6-205), many hunters do. *Trichinella* infected lion meat that has been cooked to at least 165 degrees Fahrenheit is safe for human consumption (Western Wildlife Disease Workshop 2009).

Precautions protecting against the ingestion of other rare, but potentially fatal, air or blood-borne pathogens (i.e. pneumonic plague) should also be taken when handling a harvested lion carcass or one encountered in the field (Wong 2009). Pathogen infections or disease epizootics are not known to limit wild mountain lion populations in Montana.

EFFECTS OF HUNTER HARVEST

Mountain lion reproduction (age at first parturition, maternity, interbirth interval, litter size) and annual non-harvest mortality rates are remarkably consistent across western North American populations. Reproduction and non-harvest survival are also generally unaffected by hunter harvest. However, harvest can be additive to other forms of mortality and is often the most important factor affecting population size and growth in areas where harvest occurs. Lion populations are particularly sensitive to changes in adult female harvest rate (Anderson &

Mountain lion feeding on deer kill, D. Neils

Lindzey 2005, Stoner et al. 2006, Robinson et al. 2008, Cooley et al. 2009, Robinson et al. 2014).

Local mountain lion populations that are reduced by harvest can recover rapidly. Populations that are below prey limited densities can increase up to 30% annually when harvest (especially of females) declines and lions from other areas are able to immigrate (Ross & Jalkotzy 1992, Sweanor et al. 2000, Jenks 2011, Clark et al. 2014a). For example, in Utah, mountain lion densities that were reduced >60% over a 6-year period recovered to pretreatment levels after 5 years of reduced hunter harvest (Stoner et al. 2006). In New Mexico, an adult population that was experimentally reduced by >50% fully recovered in 31 months (Logan & Sweanor 2001), and in Wyoming a population that was lowered >40% by heavy harvest recovered in 3 years after harvest was reduced (Anderson & Lindzey 2005).

Montana lion populations are similarly resilient. Lion numbers in the Garnet Mountains declined nearly 50% during a period of heavy harvest but fully recovered within

5 years after the harvest rate was reduced there and in surrounding areas (Robinson et al. 2014).

The influence of dispersal and immigration on mountain lion population growth cannot be overemphasized. Even heavily hunted local populations may fail to decline if immigrants readily replace harvested lions (Cooley et al. 2009). On the other hand, a population (such as the one within the Garnet Mountains study area) may recover more slowly where high harvest rates are applied across a broader landscape.

Harvest can also alter a population's age structure. However, the interpretation of trends in the age of harvested mountain lions may be confounded by immigration, hunter selectivity, harvest regulations, and other factors. Monitoring changes in harvest-age composition can be a useful indication of a population's status in some cases. In general, the proportion of older age-class mountain lions in harvest—especially females—is higher within growing populations (Anderson & Lindzey 2005, Stoner et al. 2006, Wolfe et al. 2015). This index

should only be used when monitored over a period of 3 or more years (Anderson 2003), and after considering other factors (i.e. immigration and harvest) that may be influencing age-at-harvest.

Within a lightly hunted lion population in western Montana's Bitterroot Mountains, 60% of independent aged lions were female (Proffitt et al. 2015). This is similar to the proportion of juvenile (13-24 month) females documented during a 10-year study of a lion population in west-central Montana, although the proportion of adult males to females varied widely during the study period depending on the level of hunter harvest (Robinson et al. 2014). Male:female ratios of 1:2 to 1:3 were commonly reported in other hunted populations (Hornocker & Negri 2009).

MOUNTAIN LION-PREY INTERACTIONS

The relationship between mountain lion predation and their prey populations is complex. This is especially true in Montana where lions often occupy multi-predator/ multi-prey species systems. Mountain lions are the most influential ungulate carnivore across much of the state,

especially where grizzly bears and wolves are absent or recovering. Therefore, wildlife managers must carefully consider the potential effects of mountain lion predation on prey populations when developing management prescriptions for both.

Mountain lions are opportunistic and adaptable foragers that prey or scavenge on a variety of species (Bauer et al. 2005, Murphy & Ruth 2011). In Montana, lions are obligate ungulate predators primarily preying on deer and elk. Mountain lion diet varies across the state depending on available prey, and lions may switch preferred prey seasonally as ungulate newborns become available or ungulate distribution changes (Williams 1992, Murphy 1998, Kunkel et al. 1999, Ruth & Buotte 2007). Mountain lions may also increasingly prey on pets, livestock (Torres et al. 1996), or other wildlife species (Logan & Sweanor 2001) following a significant decline in wild ungulate populations. Where hunter harvest is not an overriding factor, mountain lion densities are ultimately regulated by prey availability (Pierce et al. 2000a, Logan & Sweanor 2001, Stoner et al. 2006).

Mountain lion feeding on elk kill, western Montana, E. Bradley

GENERAL PREDATOR-PREY RELATIONSHIPS

In theory, compensatory predation removes a number of prey animals from a population that would have died anyway from another cause. Additive predation removes prey that would have otherwise survived. Predators regulate prey populations when the rate at which they remove prey changes along with prey population levels. Predation can limit prey population growth if the predation rate is independent of changes to a prey species' abundance—in these cases, predation can depress, rather than stabilize, prey populations.

Predation is more likely to limit a prey population when 1) an alternative and abundant prey species supports high predator densities, 2) prey is below carrying capacity despite weather and habitat that allow adequate survival and recruitment, and 3) there is a high predation rate relative to recruitment.

Predators can limit prey populations when predation is additive to other sources of mortality (i.e. severe weather or starvation). For example, in Idaho, when experimental mountain lion removals immediately increased mule deer fawn and adult survival, the effect of mountain lion predation initially appeared to be additive. However, reducing lion densities did not significantly affect overall deer population growth. In this case, weather and annual changes in forage quality ultimately regulated mule deer numbers — mountain lion predation was, in fact, compensatory over the long term (Bishop et al. 2009, Hurley et al. 2011).

In systems where most prey biomass is composed of a single, fecund, species (e. g. white-tailed or mule deer), predation itself is unlikely to depress prey populations for extended periods. However, when severe weather or other factors decrease populations significantly below habitat carrying capacity, mountain lion predation can delay the prey species' recovery (Ballard et al. 2001, Logan & Sweanor 2001, Pierce et al. 2012).

Where predator populations are sustained at high densities by an abundant prey species, populations of other relatively vulnerable or scarce prey species might decline or remain depressed (Messier 1994, Mills 2007). This

Montana includes some of the most highly productive mountain lion habitat in North America

apparent competition (Holt 1977) has been implicated in declines of mule deer (Robinson et al. 2002, Cooley et al. 2008), bighorn sheep (Logan & Sweanor 2001), mountain caribou (Kinley & Apps 2001) and other species (Sweitzer et al. 1997) due to lion predation.

Winter severity explained most variation in annual white-tailed deer recruitment in northwest Montana. There, when harsh winter weather depressed reproduction and survival of hunted deer, predation (primarily by lions) became additive to other forms of mortality and exacerbated population declines (Montana Fish, Wildlife & Parks 2006).

Mountain lion kill rates vary by location and ecological system, but are generally reported as 1 kill per 7 days in deer dominated systems and 1 kill per 10 days in systems where elk are also available (Murphy 1998, Anderson & Lindzey 2003, Cooley et al. 2009). Lions tend to kill more frequently in warmer months, when ungulate newborns are available, and when competition with or rates of displacement by other predators is high.

Predation rates also vary depending on a mountain lion's age, sex, and reproductive status. Adults kill prey more frequently than younger lions. While adult females with dependent kittens exhibit the highest kill rate of any lion age/sex class, adult males kill a greater prey biomass on an annual basis (Nowak 1999, Buotte et al. 2008, Clark et al. 2014b). In Alberta, the annual live weight biomass of prey killed by mountain lions averaged 3,180 lbs. for subadult females, 4,520 lbs. for subadult males, 10,380 lbs for adult males, 5,340 lbs. for adult females, 6,160 lbs. for females with kittens < 6 months, and 9,440 lbs. for females with kittens > 6 months (Knopff et al. 2010).

Deer are the most common mountain lion prey species in Montana. In northwest Montana's Salish Mountains, lions were the most common predator of radio marked white-tailed deer (Montana Fish, Wildlife & Parks 2006). Similarly, 87% of lion kills documented in Montana's North Fork of the Flathead River drainage were white-tailed deer, where elk, mule deer, and moose were also present in lower numbers (Kunkel 1999).

However, in northeast Washington mountain lions disproportionately selected for mule deer even though white-tailed deer were more abundant (Cooley et al. 2008). The same was true in south-central British Columbia where mountain lion predation was implicated in mule deer declines (Robinson et al. 2002). Where both elk and mule deer were present, female mountain lions were more likely to kill mule deer, whereas male mountain lions killed elk more frequently (Anderson & Lindzey 2003). Female lions may also select for calf elk and younger or older mule deer (Nowak 1999, Pierce et al. 2000b).

Although most researchers found that mountain lions selected for male elk and deer (Hornocker 1970, Kunkel et al. 1999, Anderson & Lindsey 2003, Atwood et al. 2007, Blake & Gese 2016), others did not (Clark et al. 2014b). Adult male elk and deer are more often killed by mountain lions during and after the rut while most adult female elk and deer are killed before giving birth in late spring (Knopff et al. 2010, Clark et al. 2014b).

The annual risk of mountain lion predation to adult female elk across the western U. S. (Brodie et al. 2013) and in Montana (Hamlin & Cunningham 2009, Eacker et al. 2016) is low compared to other sources of mortality, including hunting. This is important because, in certain situations, adult female survival explains more of the variation in overall elk population growth rate than elk calf survival (Eacker et al. 2017).

Lions are often one of the primary predators of elk during their first year of life. The rate of calf predation by mountain lions increases with overall lion density, decreases when other predators (especially wolves and grizzly bears) are abundant, and increases when herds are nutritionally limited and concentrated during winter (Kortello et al.

2007, White et al. 2010, Griffin et al. 2011, Johnson et al. 2013, Eacker et al. 2016).

Elk calf survival and recruitment can influence a herd's growth and, subsequently, the number of elk available for hunter harvest (Raithel et al. 2007). Although calf survival does not appear to be strongly influenced by the physical (nutritional) condition of cow elk, poor forage on summer range can reduce a herd's pregnancy rate (Reardon 2005, Proffitt et al. 2016). Depressed calf production may then predispose that herd to the effects of mountain lion predation and exacerbate population declines (Clark et al. 2014b, Eacker et al. 2016).

Unlike bears, which primarily kill elk calves during the first 30 days of life, mountain lions prey on them throughout the year. Mountain lions were responsible for 70% of elk calf mortalities in northeastern Oregon where there are black bears but no wolves or grizzly bears (Reardon 2005). On a study site in western Montana where there were wolves

**Wildlife managers

management
prescriptions
for both**

and black bears (but no grizzlies), Eacker et al. (2016) found that 60% of known cause calf mortality was by mountain lions and male calves were 50% more likely to die than females.

Elk migration to areas of greater or lesser exposure to predation can also affect calf survival (Hebblewhite & Merrill 2007). For example, in Montana, seasonal migration of elk to ranges dominated by agriculture (where predators were rare) lowered predation risk while concentration on winter ranges increased it (Eacker et al. 2016).

The density of mountain lions in an area may itself be enough to explain predation's influence on elk calf recruitment. Where mountain lion densities are high they are capable of limiting elk recruitment enough that annual variation in lion densities explains most of the variation in annual calf survival (Johnson et al. 2013). In Montana's Bitterroot Range, where lion densities were relatively high, grizzlies absent, and wolves were present, lion predation accounted for most calf elk mortality (Eacker et al. 2016). In contrast, on Yellowstone's Northern Range and in Montana's Garnet Mountains where mountain lion density was relatively low, the rate of lion predation of elk calves was also low (Raithel 2005, Barber-Meyer et al. 2008).

The effect of mountain lion predation on bighorn sheep populations varies, but is most likely to limit population growth where herds are small and isolated (Ruth & Murphy 2011). The rate of predation can simply be a function of the overall mountain lion density within a sheep herd's range. However, in some cases bighorn sheep predation is a specialized behavior adopted by individual lions (Logan & Sweanor 2001).

Lion predation of bighorn sheep can increase where lion densities are buoyed by an abundant primary prey species or when a decline in the primary prey causes lions to switch to bighorn sheep (Kamler et al. 2002). Targeted removals of individual lions that specialize on sheep, or sustained efforts to suppress lion density in core bighorn sheep habitat, can effectively reduce the impact of lion predation on small, isolated herds (Ernest et al. 2002, McKinney et al. 2006).

MANAGEMENT CONSIDERATIONS

- Weather and forage availability are more likely than predation to explain chronically low ungulate populations. The influence of these potentially limiting factors should be evaluated before predation is implicated.
- Mountain lion predation is more likely to limit a prey population's growth if that population is below habitat carrying capacity and the lion predation rate is high. For instance, if a severe winter causes a significant deer die off but overall forage availability remains unchanged, mountain lion predation may slow the herd's recovery. In this case, preemptively and temporarily reducing mountain lion density through hunting could increase the deer population's growth rate while potentially reducing human-mountain lion conflicts.
- Mountain lion predation can limit a prey population where lions are the most abundant predator, lion density is supported by another abundant prey species, and the prey population is below its habitat's carrying capacity. In this case, managers should consider whether apparent competition is the ultimate cause of a secondary prey species' (e.g. mule deer or bighorn sheep) decline. Where abundant primary prey support dense mountain lion prey populations, sympatric populations of more vulnerable secondary prey may be disproportionately affected.
- The effect of predation on elk survival increases with the diversity of the predator community – the addition of grizzlies and wolves to a system with established mountain lions and black bears can change the influence of predation on ungulate prey.
- Mountain lion predation is unlikely to limit adult elk survival but can significantly reduce elk calf recruitment where lions are the predominant predator, lions occur at high densities, and where weather and/or habitat quality has reduced elk pregnancy rates.

- Targeted removal of individual lions that specialize on bighorn sheep, or sustained efforts to suppress lion density in core bighorn sheep habitat, may reduce the influence of mountain lion predation on the growth of small and isolated sheep herds.

- Attempts to locally reduce mountain lion populations will likely be confounded by the effect of immigration. Harvest treatments intended to reduce lion density should be sustained, broad scale, or both.

- Any proposal to reduce mountain lion density to benefit prey should be explicitly developed in an adaptive management framework. Managers should make measurable predictions about the outcome of a mountain lion harvest prescription (on lion and prey populations), monitor and evaluate the treatment's effects after a predetermined period, and be prepared to modify management based on that evaluation.

CHAPTER 2

MOUNTAIN LION-HUMAN CONFLICT

Montana law grants FWP and the Fish and Wildlife Commission broad authority and discretion to manage wildlife. However, the legislature provided specific direction to the Department regarding the management of large predators, including mountain lions, that clearly emphasizes the protection of people and property over sport hunting of either mountain lions or their prey:

87-1-217. Policy For Management Of Large Predators - Legislative Intent

(1) In managing large predators, the primary goals of the department, in the order of listed priority, are to:

- (a) protect humans, livestock, and pets;
- (b) preserve and enhance the safety of the public during outdoor recreational and livelihood activities; and
- (c) preserve citizens' opportunities to hunt large game species.

A mountain lion becomes a public safety concern when it appears habituated to human activity or development, attacks livestock or pets, or in any way behaves aggressively toward humans. FWP has developed specific Mountain Lion Depredation and Control Guidelines (Appendix 3) which describe and direct the Department's actions following a reported conflict between a human and a mountain lion.

The types and rate of conflicts between mountain lions, humans, and livestock are affected by mountain lion abundance, location, presence of attractants, and individual lion behavior. FWP will rely on the expertise and judgment of its field staff and agents (i.e. USDA Wildlife Services

personnel) to investigate reported conflicts and determine the most appropriate response to a given situation. FWP's principal consideration when making these decisions will be reducing future risk of harm to people and/or property.

FWP will respond to human-lion conflicts in a manner that protects public safety, reduces property loss, and increases public tolerance for mountain lions. FWP will enforce state law (MCA 87-6-216) and local ordinances that prohibit certain wildlife attractants and will work to remove or contain attractants when a lion localizes in a problematic location. FWP will use hunter harvest when and where appropriate to manage lion density in high conflict areas. Finally, FWP may use targeted hazing or removal of individual offending mountain lions to mitigate ongoing or potential risk to people, pets, or livestock.

FWP will implement and facilitate programs that help livestock and pet owners protect their animals such as those currently offered by FWP, the Montana Livestock Loss Board, and nongovernmental organizations. FWP will continue to emphasize the importance of preventative efforts intended to reduce the risk of livestock loss in memoranda of understanding entered into with USDA Wildlife Services.

FWP does not maintain facilities to rear, hold, or rehabilitate mountain lions. Mountain lions that are injured so severely that they could pose a risk to humans or those that are unlikely to survive without intervention will be euthanized.

Montana hunting regulations prohibit the taking of a female lion accompanied by spotted kittens. However, in the unfortunate circumstance that a lactating female lion is mistakenly taken by a hunter or is otherwise killed, FWP staff may attempt to find the kittens and humanely euthanize them, unless an approved zoo or other facility is prepared to permanently assume responsibility for their care.

Capturing and relocating habituated, aggressive, or depredating mountain lions is not an effective conflict management response (Hornocker & Negri 2009). Mountain lions that are captured and translocated are

unlikely to survive, often return (or attempt to return) to their capture location (Ross & Jalkotzy 1995, Ruth et al. 1998), and can cause future conflicts (Belden et al. 1991, Williams 1992). For these reasons, mountain lions shall not be captured and translocated under any circumstances. Mountain lions involved in any form of conflict will be dealt with per the Mountain Lion Depredation and Control Guidelines (Appendix 3).

Statewide records of reported mountain lion-human conflicts are historically incomplete (Table 2). In 2007, FWP created a centralized database to track harvest and most reported human caused non-harvest lion mortality. The same database has since been updated to also archive records of animals, including mountain lions, that are incidentally caught by recreational trappers and successfully released. This system will also be used to record all reported human-mountain lion conflict incidents, and their resolution. These more complete records will allow FWP to identify sources of and trends in mountain lion conflicts so that they can be more effectively addressed.

FWP actively educates the public about safely living with mountain lions, avoiding human-lion conflicts, and reducing the risk of property loss. The agency will continue to employ biologists and technicians who specialize in educating the public about, and responding to, human-predator conflicts. FWP will also maintain and periodically update educational materials and programs that teach the public about lion biology and behavior, ways to avoid and diffuse conflicts, strategies and methods to protect pets and livestock, and how to responsibly live and recreate in mountain lion habitat.

LIVESTOCK DEPREDATION

Mountain lions were confirmed to have killed an average of 136 head of livestock in Montana annually between 2006 and 2015 (USDA Wildlife Services, Table 3). However, only a fraction of actual livestock losses to mountain lions are found and formally documented (Jenks 2011). In Montana, male mountain lions were more likely than females to be removed in response to livestock depredation and most depredating lions were younger adults (1-4 years old) in good physical condition. The peak time period for both

Mountain lion killed following domestic sheep depredation, FWP

The rate of livestock loss may be partly a function of an area's mountain lion density

livestock and human conflict incidents was between June and November (Riley & Aune 1997).

Mountain lions most commonly kill livestock that weigh less than 300 pounds. Although full grown cattle and horses are occasionally killed, mountain lions mainly kill calves/foals and yearlings. Losses are highest where calves or foals are born in lion habitat (Cougar Management Guidelines Working Group 2005). Small livestock (sheep, goats, and fowl) are the domestic species most vulnerable to mountain lion predation in Montana (Figure 3). Livestock depredation predominately occurred in central Montana where sheep production is more common and in western valleys where there is a greater number of hobby livestock.

Montana law (MCA 87-6-106) allows private citizens to legally kill any mountain lion that is attacking, killing, or threatening to kill a person or livestock. Private citizens may also legally kill a mountain lion that is in the act of

attacking or killing a domestic dog. A person who kills a mountain lion under this statute must notify a FWP employee within 72 hours and surrender the carcass. FWP may issue a permit to kill a mountain lion to a landowner which allows them to take a mountain lion, within a specific area and time period, that is threatening to or suspected of killing livestock.

FWP annually contracts USDA Wildlife Services to respond to reported depredation of commercial livestock. When a loss is reported, a Wildlife Services agent conducts a field investigation to determine whether the loss is a “probable” or “confirmed” depredation and what predator species is responsible. Based on that investigation, and whether predation is determined to be the likely cause, the agent decides what response is most likely to prevent further livestock losses. This may, but does not always, include attempting to lethally remove the offending individual predator. The annual FWP contract requires Wildlife Services to provide records of all reported incidents (including lethal removals) to FWP at the end of the federal fiscal year (October 1).

Montana's Livestock Loss Board may reimburse stock growers for up to fair market value of probable or confirmed livestock losses due to mountain lion predation. The Board may also issue grants supporting efforts to reduce or mitigate the risk of mountain lion depredation of livestock (MCA 2-15-3110 through 3113).

Table 3. Domestic livestock reported to and/or verified by USDA APHIS Wildlife Services as injured or killed by mountain lions, federal fiscal years 2006 – 2015.

The rate of livestock loss may be partly a function of an area’s mountain lion density. In Oregon, Hiller et al. (2015) found that as mountain lion population density increased, so did the number of mountain lions killed as a result of livestock predation. This relationship was especially strong at higher mountain lion densities. Livestock conflicts either decreased when mountain lion hunter harvest increased or remained constant where mountain lion densities were relatively low.

There is evidence that a similar relationship between lion abundance and livestock conflict may exist in Montana. There is a correlation ($r^2 = 0.66$) between the number of mountain lions that Wildlife Services agents annually killed in response to livestock depredations and the statewide mountain lion population estimated by FWP’s Integrated Population Model (1990 – 2013; Chapter 6; Figure 4). Hunter harvest that maintains mountain lions at moderate densities may be a useful tool in managing livestock predation in some circumstances (Hiller et al. 2015).

Otherwise, there are few practical measures that can completely prevent the loss of commercial livestock to mountain lions. Delaying turnout of cow-calf pairs into remote lion occupied pastures may reduce calf loss. Although guard dogs can reduce livestock losses to canine predators, guard dogs do not effectively protect against mountain lion depredation (Jenks 2011). If economically feasible, switching from raising small livestock (i.e. sheep)

Figure 3. Proportion of livestock killed by mountain lions by species, 2006 – 2015.

to less vulnerable species where mountain lions are common may also reduce depredation losses (Lindzey 1987). Owners of hobby livestock can effectively use practices unavailable to commercial producers such as night penning, lights, and clearing brush around paddocks to reduce depredation risk.

MOUNTAIN LION-HUMAN INTERACTIONS

Mountain lion attacks on humans in Montana are extremely rare. The only fatal mountain lion attack in modern times was that of a 5-year old boy killed near Evaro, on the Flathead Indian Reservation, in September of 1989. Several nonfatal attacks have also occurred in the state and, like elsewhere, overwhelmingly involved children (Beier 1991). Juvenile and subadult mountain lions are responsible for most human-lion conflicts across the western U. S. (Mattson 2007), including Montana.

Subadult lions of both sexes are also more likely than adults to use urban and exurban residential areas (Kertson et al. 2013). Although in Montana males were more likely than females to take livestock, sex ratios of lions involved in human incidents were not significantly different from 50:50. Human incidents mostly occurred near western intermountain valley communities.

Mountain lions commonly live adjacent to, or travel through, developed areas but most lions travel at night and are rarely seen (Kertson et al. 2013). Individuals that are routinely sighted during daylight hours near homes and people, or those that appear accustomed to human activity and development, have become habituated and are a public safety concern. Individual lion behavior

**Mountain lions

travel at night and are
rarely seen**

often escalates from natural to habituated to nuisance to dangerous, at which point the lion may begin to kill pets in populated areas and/or to display aggression toward humans (Cougar Management Guidelines Working Group 2005).

If an investigation reveals that a habituated mountain lion has become a nuisance or aggressive, FWP staff should document the behavior, notify area residents of the situation (especially those with children and/or outdoor pets), and immediately attempt to either aversively haze or lethally remove the offending individual.

Field staff should closely follow the approved protocols for responding to human-lion conflicts in the Mountain Lion Predation and Control Guidelines (Appendix 3).

SPECIAL MANAGEMENT AREAS

Montana has designed certain Lion Management Units (LMUs) specifically to encompass urban, suburban, or agricultural areas where the tolerance for mountain lion presence is low and the potential for human-mountain lion conflict is high. The Commission may designate these LMUs “Special Management Areas” (described by Logan & Sweanor 2001) and either elect to assign an “unlimited” harvest quota (e.g. LMU 170, immediately surrounding Kalispell) or a high annual quota that it is rarely, if ever, met.

If a Special Management Area contains suitable mountain lion habitat, the management approach may not significantly reduce mountain lion densities because of

rapid immigration into vacated home ranges (Robinson et al. 2008, Cooley et al. 2009). However, specifically designating Special Management Areas can ease social and political concerns (Jenks 2011) and, importantly, ensure that legal hunter harvest remains a management tool throughout the fall and winter hunting seasons.

For example, the Missoula Special Management Area (MSMA), a LMU surrounding the highly developed Missoula Valley, was established in 1994. Relatively high quotas in this LMU are rarely met even though the area contains high-quality lion habitat and General License hunting was allowed for nearly 7 months each year.

The average age of a mountain lion harvested within the MSMA between 2000 and 2015 (3.09 years; n = 421) was slightly lower than that of lions harvested during the same period in the remainder of Region 2 (3.58 years; n = 2319). However, this small difference does not indicate that higher hunter harvest opportunity meaningfully increased the proportion of more conflict prone juveniles in the LMU. Although FWP staff lethally removed several nuisance mountain lions from the MSMA each year, FWP hunting regulations were not publicly perceived as limiting legal hunter harvest during established seasons in this high conflict area.

Figure 4. The relationship between Montana’s modeled mountain lion population trend and annual mountain lion removals by Wildlife Services in response to livestock depredation, 1989 - 2013.

CHAPTER 3

2016 MONTANA MOUNTAIN LION RESOURCE SELECTION FUNCTION

INTRODUCTION

To produce accurate estimates of mountain lion abundance, managers first need to understand what habitat features are important to lions and how that habitat is distributed across the state. Accurate spatial models that describe mountain lion habitat use can also be used to monitor lion populations over time. While producing reliable maps of relative mountain lion habitat quality and landscape linkages is critically important (Cougar Management Guidelines Working Group 2005, Jenks 2011) they have previously been difficult to produce and validate.

Managers need accurate spatial data that depict mountain lions' use of their habitat in order to predict lion abundance and to monitor their populations over time

Montana FWP will use a “resource selection function” (RSF) model to depict and analyze the state’s mountain lion habitat. A RSF is a statistical model that represents the relative probability that an animal will select a particular place or resource (Manly et al. 2002). A RSF is simply a spatial surface of pixels or cells that are each assigned a statistical value based on what we know about a species’ habitat selection. This surface can then be used to mathematically analyze and describe the species’ habitat use at larger scales.

A RSF is often displayed as a map showing the relative likelihood a species will use a particular resource or available habitat. Biologists construct RSFs from field data that describe an animal’s spatial use (such as telemetry relocations collected using radio or GPS collars) and the habitat variables that likely cause the animal to select (or avoid) certain resources or areas. Habitat variables may include vegetation type, canopy closure, elevation, terrain, or other features that affect an animal’s habitat selection.

It’s impossible to quantify all the habitat variables that cause an animal to select a certain location. However, we can often identify a combination of measurable factors that accurately predict the relative likelihood that a species is present in a certain habitat type. If we also have information about a population’s vital rates and population density, we can also estimate how many individuals a larger area likely supports.

A well designed RSF can help biologists better manage wildlife in many important ways. RSFs can describe the kind of habitat where we’d expect to find a certain species, map corridors that are potentially important connections between larger habitat patches, and identify isolated areas of suitable habitat that may support a species, even if the species is not currently there. RSFs help managers identify resources that are important for the conservation of a species or that may be limiting its use of an area. Finally, a RSF allows biologists to make inferences about an animal’s abundance across broad landscapes using monitoring data that provides information on the population’s current density.

FWP will use a statewide mountain lion RSF to:

1. Define distinct mountain lion ecoregions. The RSF surface consists of many small cells, or “pixels”, that are each assigned a value based on the habitat features present within them. The average RSF value of all the pixels within a hunting district or lion management unit generally describes the overall quality of that unit’s lion habitat. FWP used these average values to define large, biologically meaningful, ecoregions within the state where lion habitat is similar in type and

distribution. These ecoregions will be the primary spatial basis of its mountain lion population monitoring program (Chapter 4).

2. Improve population monitoring.

The RSF helped FWP identify representative population Trend Monitoring Areas within the Northwest, West-central, and Southwest ecoregions. The RSF will also be used to guide periodic field sampling within these Monitoring Areas (Chapter 4).

3. Enable FWP to estimate mountain lion abundance.

When the relationship between observed lion abundance and the RSF is known, we can estimate lion abundance within both Trend Monitoring Area(s) and the larger ecoregion. Integrating the RSF with field sampling such as spatial capture-recapture (Chapter 5) makes these monitoring methods more effective. Including a RSF as a covariate in the density estimation model—that is, formally assuming that an animal's activity center is more likely to fall in higher quality habitat—significantly improves the population estimate's biological realism and precision.

MONTANA MOUNTAIN LION RESOURCE SELECTION FUNCTION

Robinson et al. (2015) produced the first comprehensive winter mountain lion resource selection function for the state of Montana. The authors used mountain lion telemetry relocations (both VHF and GPS) from 10 individual mountain lion field research projects conducted throughout Montana and Yellowstone National Park between 1979 and 2012 to train and validate the RSF (Table 4). A significant number of telemetry locations were withheld from the training data for internal model validation. Mountain lion harvest locations (1988 – 2011; generalized to the center of the 640-acre section of harvest) were also used to validate the model. The original manuscript contains a detailed description of how this original RSF was constructed, was tested, and performed.

The most important measure of a RSF's utility is its ability to predict a species' use of available habitat (Boyce et al. 2002). The 2015 RSF model predicted both out-of-sample lion telemetry locations and hunter harvest locations quite well across Montana. Although there was generally excellent agreement between the location of harvested animals and predicted areas of lion habitat use, the 2015 model was most predictive in FWP Regions 1, 2, 4 and 6. In Regions 3, 5, and 7, a higher proportion of animals were harvested in areas that the RSF predicted to be lower quality habitat, compared to other FWP Regions.

Table 4. Field studies and sampling data used to develop the Robinson et al. (2015) and 2016 MT Mountain Lion Resource Selection Function.

2016 MONTANA MOUNTAIN LION RSF

In 2016, FWP and Dr. Robinson worked together to improve the mountain lion RSF's ability to predict lion habitat selection statewide — specifically, in southern and eastern Montana. The same methods used by Robinson et al. (2015) were used to develop a revised version of the RSF, with three important refinements:

1. All available mountain lion telemetry relocations (n = 22,595) from the 10 Montana and Yellowstone National Park studies were used to train the revised model. "Study Area" was then used in the Generalized Linear Model as a random effect to account for varying levels of sampling intensity amongst studies.
2. FWP reexamined approximately 3,800 individual harvest locations reported between 2007 and 2015 - hundreds of location errors were found and corrected. The more accurate and complete 1988 – 2015 harvest data set (totaling 10,503 mountain lion harvest locations) was then used for external validation of the refined winter RSF model.

3. The revised winter RSF contained the same variables as described by Robinson et al. (2015) except that the variable "distance to forest" was replaced by a quadratic of "canopy closure" (Table 5). The revised model included a random intercept for each study area/data set.

We refer to this refined model (Figures 5 and 6) as the 2016 MT Mountain Lion RSF and it is the model used throughout this Strategy. The 2016 RSF performed similarly to Robinson et al.'s original 2015 model in FWP Regions 1, 2, 4, and 6 while the agreement between harvest locations and predicted high-quality habitat in Regions 3, 5 and 7 was significantly improved (Figure 7).

It is important to note that the RSF does not describe all the variables that affect mountain lion distribution or abundance. There are factors such as prey density, habitat disturbance (i.e. wildfire), or harvest history that are important to mountain lions and that vary over time. Therefore, it will be necessary to periodically reassess the relationship between the RSF and actual mountain lion density in an area (as described in Chapter 5).

CHAPTER 4

MONTANA MOUNTAIN LION ECOREGIONS

Mountain lions currently occupy nearly all of their suitable habitat in Montana. However, the quality, quantity, and arrangement of that habitat—thus the number of lions an area can support—varies significantly across the state. Mountain lion habitat in northwest Montana is nearly continuous, but habitat quality generally declines and becomes patchily distributed in more southern and eastern portions of the state (Figure 5).

The average RSF values of individual Lion Management Units reflects this pattern (Figure 8). This gradient in lion habitat quality across Montana allowed FWP to partition the state into distinct mountain lion “ecoregions”. These ecoregions are large, contiguous areas of the state within which lion habitat is broadly similar. Mountain lion ecoregions are the spatial basis of FWP’s lion population monitoring program.

Mountain lion harvest management is most effective when it’s done at a large and biologically meaningful scale (Cougar Management Guidelines Working Group 2005, Jenks 2011). In lightly hunted populations, virtually all males and a significant proportion of females disperse from their natal area. Lion populations are best thought of as many connected sub-populations linked by dispersing animals. Local areas generally depend on immigration to recruit breeding males and, often, a large portion of breeding females.

These local sub-populations (i.e. within a LMU) can be resilient to harvest because lions are able to readily emigrate from adjacent areas and refill available habitat. Dispersal can also cause local populations to exhibit lower growth rates than expected, given their intrinsic vital rates (Sweanor et al. 2000, Logan & Sweanor 2001, Stoner et al. 2006, Cooley et al. 2009, Robinson et al. 2008 & 2011, Newby et al. 2011). Therefore, even if a LMU’s harvest rate appears sustainable (when supported by immigration), the same harvest level could cause the unit’s population

to decline if harvest in adjacent areas increases. Similarly, specific attempts to reduce local lion populations can fail over the long term because of increased immigration from outside the treatment unit (Clark 2014a).

Monitoring and management programs are most effective when implemented across large landscapes. The effects of immigration and emigration on local population dynamics are less pronounced when considering large scale trends (Robinson et al. 2015). Importantly, large-landscape (i.e. > 35,000 km², an area ~ 115 x 115 miles) lion populations can be considered statistically “closed” (that is, the influence of immigration/emigration is eliminated) for most analyses (Robinson et al. 2008). Harvest treatments and abundance estimates are therefore less likely to be confounded by metapopulation dynamics if they are conducted across broad landscapes.

Montana includes a diverse range of habitat types, prey communities, weather patterns and other factors that affect mountain lion abundance. The relationship between an area’s lion abundance and the range of RSF values within that area is unlikely to be the same across the state. Therefore, conducting field population monitoring and modeling efforts within large but discrete ecoregions (containing similar lion habitat) helps take this habitat variability into account.

FWP can more accurately estimate broad scale (ecoregion) lion abundance when using monitoring data collected from within that same ecoregion because mountain lion habitat and harvest history is more similar within ecoregions than across them (Boyce & McDonald 1999). FWP will produce periodic estimates of lion abundance and forecast the effects of harvest based only on monitoring data collected within those respective ecoregions (Chapters 5 and 6).

Mountain lion harvest management is most effective when it’s done at a large and biologically meaningful scale

Figure 8. Avg. Mountain Lion Resource Selection Function values (0 = lowest quality habitat, 1 = highest quality habitat) for Montana's 2016 Lion Management Units.

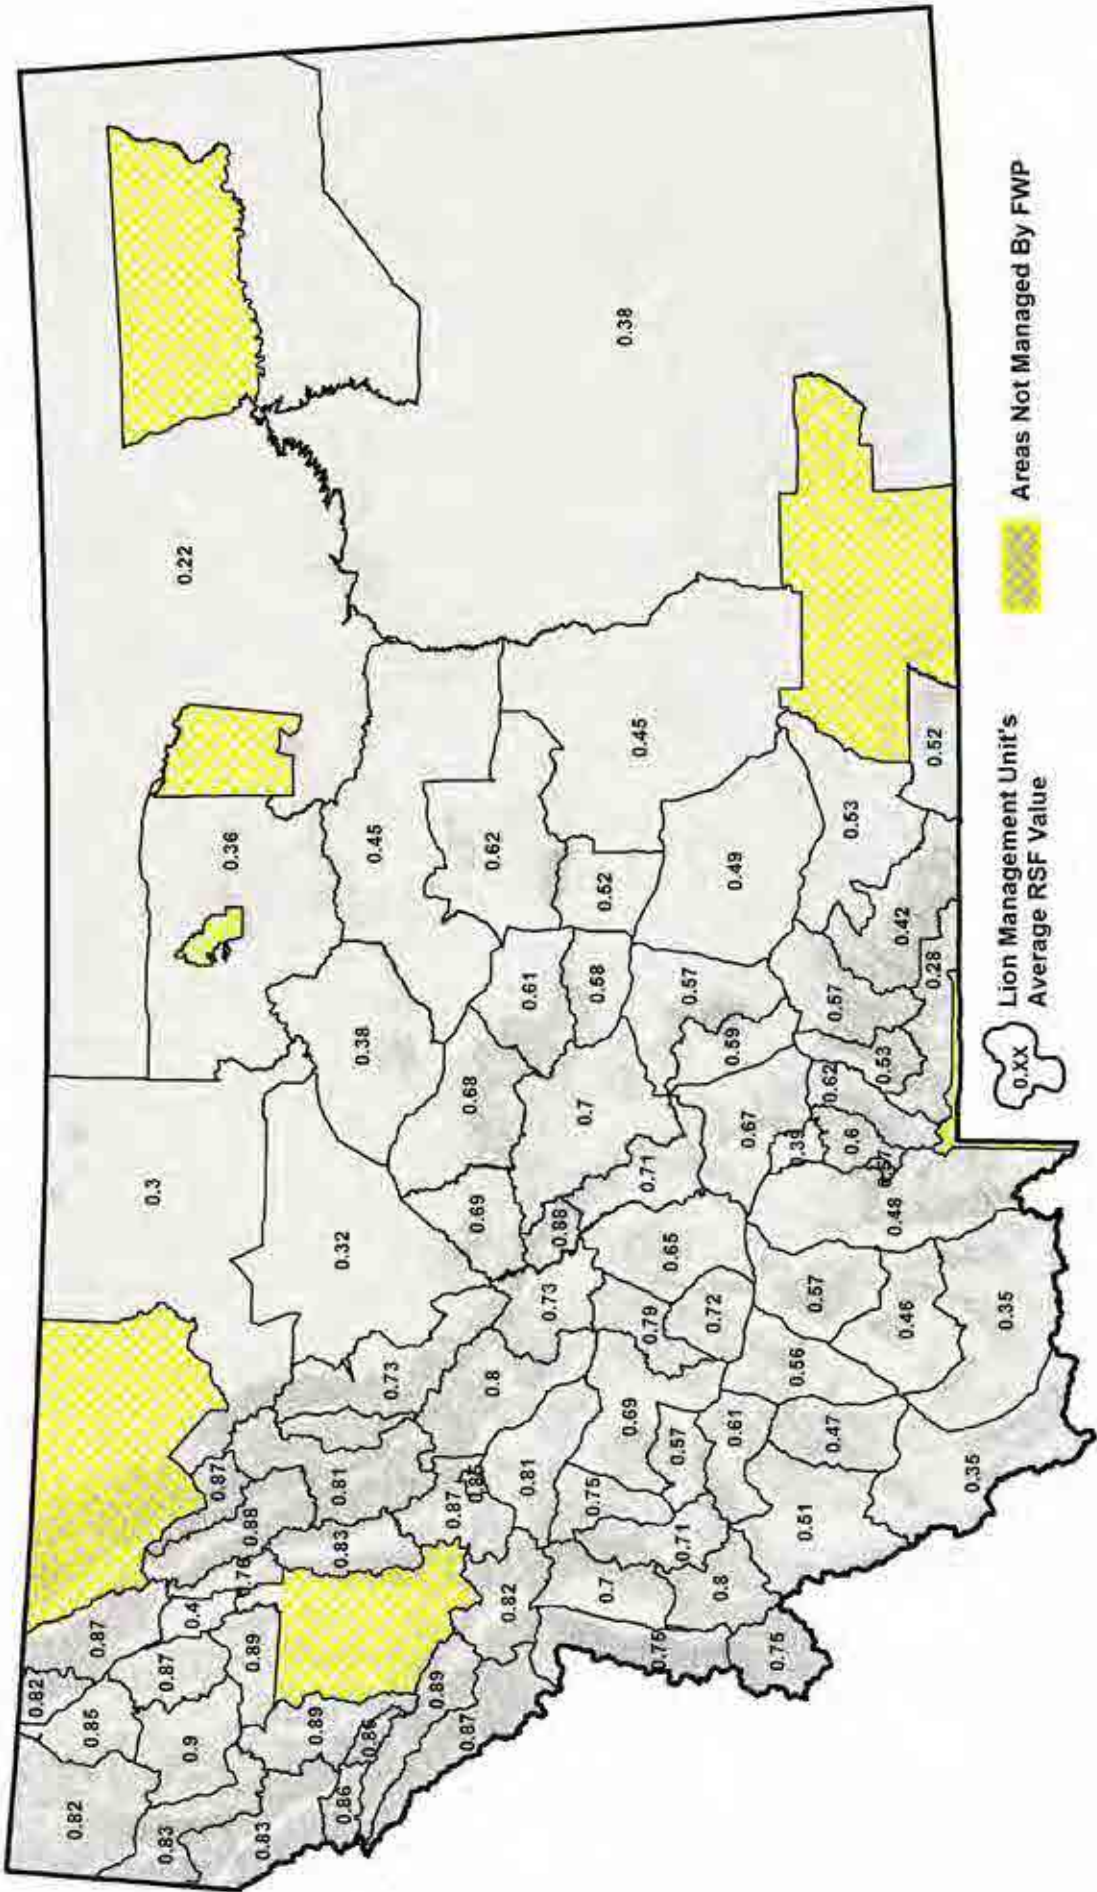

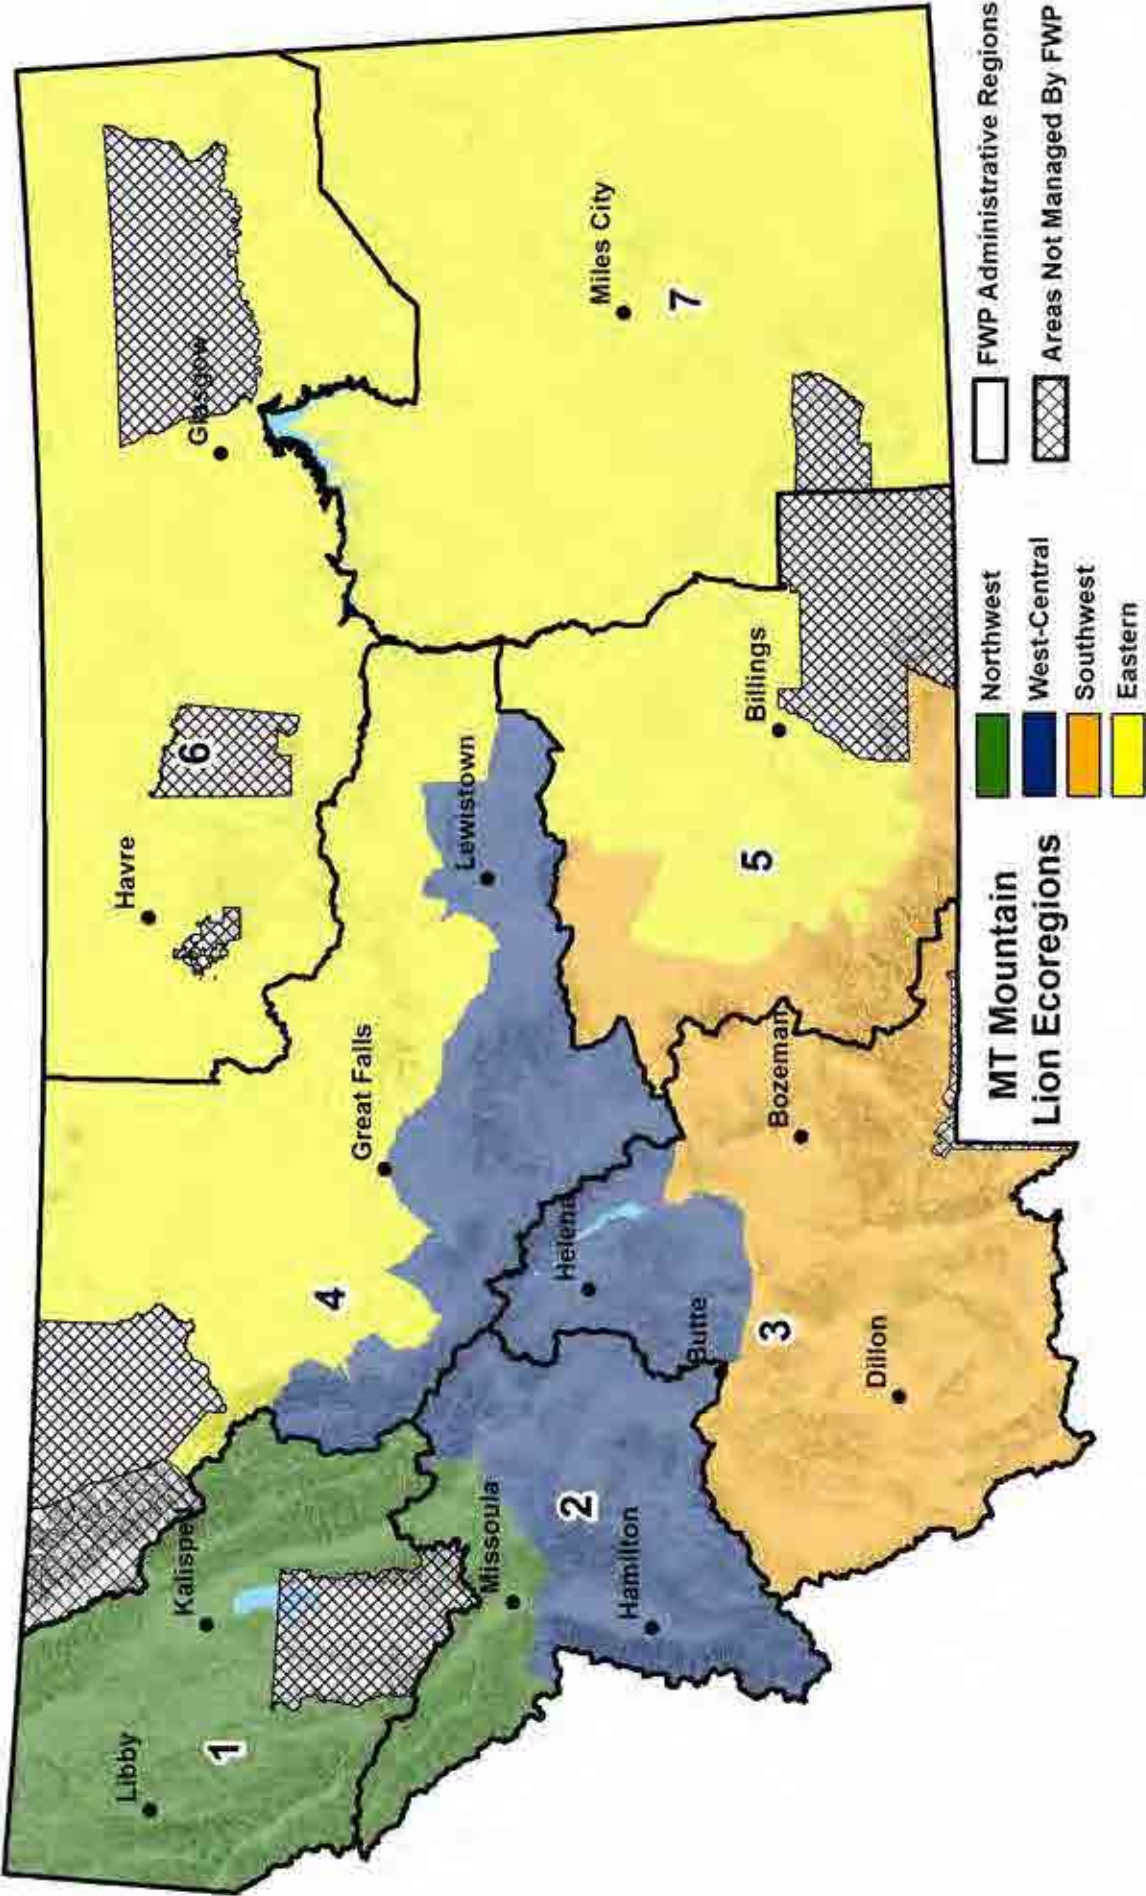

Figure 9. Montana's four mountain lion ecoregions and seven FWP administrative regions.

For the same reason, it is also only statistically and logistically practical to estimate lion population trend at a large scale. Mountain lion ecoregions should contain enough lions that populations can be modeled assuming that those populations are statistically closed. Population models then consider vital rates (from research on marked animals), harvest records, and periodic abundance estimates to allow managers to better understand past and future population trends (Chapter 6). This ability to describe the effects of past harvest and to predict the effect of future harvest prescriptions is a cornerstone of an adaptive harvest management program (Chapter 8).

FWP considered four factors when identifying individual mountain lion ecoregions:

1. They include contiguous LMUs with broadly similar habitat quality (RSF values).
2. They are large enough to allow management prescriptions to be effective despite internal lion metapopulation dynamics.
3. They are well distributed and represent the range of Montana lion habitat types.
4. The total number of ecoregions is limited so that monitoring can occur frequently enough to provide meaningful and timely data to managers. There is a tradeoff between the number of statewide ecoregions and how often each of them can be monitored. Budgets and available personnel limit the amount of effort FWP can expend field sampling lion populations.

FWP grouped 2016 LMUs' using a k-Nearest Neighbor algorithm (ESRI ArcGIS 10.1) based on their RSF values and proximity. Local biologists then helped identify four contiguous mountain lion ecoregions that met the above criteria and that could be reasonably managed as distinct units (Figure 9). FWP will periodically collect field data to produce abundance estimates for each of the three western MT ecoregions (where approximately 90% of harvest annually occurs). Estimates of future lion abundance and trend will also be modeled for these ecoregions.

Each Montana mountain lion ecoregion includes all or portions of two or more FWP administrative Regions. FWP managers and the public from different administrative Regions will collectively evaluate an ecoregion's monitoring data, develop management objectives, and decide on an overall management prescription (harvest) for the ecoregion. Managers will then recommend individual LMU harvest limits that implement the prescription, distribute hunter effort, and address local concerns.

FWP also identified a permanent population Trend Monitoring Area in each of the state's three western ecoregions. These Trend Monitoring Areas will be periodically sampled to produce estimates of lion abundance within them, and in their respective ecoregions. The criteria used to select Trend Monitoring Areas are described in Appendix 1.

To be clear, the following ecoregions will be the basis of Montana's mountain lion population monitoring program. Information about the status and trend of lion populations within these ecoregions will inform adaptive management proposals that affect lion populations at the ecoregion scale. FWP and the public in two or more FWP administrative regions will periodically collaborate to develop certain population objectives for each ecoregion. For example, biologists and the public in FWP Regions 1 and 2 may agree to an objective of a moderately positive, negative, or stable population growth rate over the following 6 years in the Northwest ecoregion.

However, biologists and the public in each of the seven FWP administrative regions have local expertise, experience, and relationships. FWP public meetings and many wildlife advocacy groups are also organized by FWP administrative region. Therefore, specific management recommendations about harvest prescriptions and season structure for individual LMUs will be developed by FWP staff and the public in each of the seven administrative regions. The cumulative effect of these individual LMU prescriptions (i.e. the overall harvest within an ecoregion) will be considered, and periodically assessed, at the ecoregion scale.

ECOREGION DESCRIPTIONS

Northwest Ecoregion

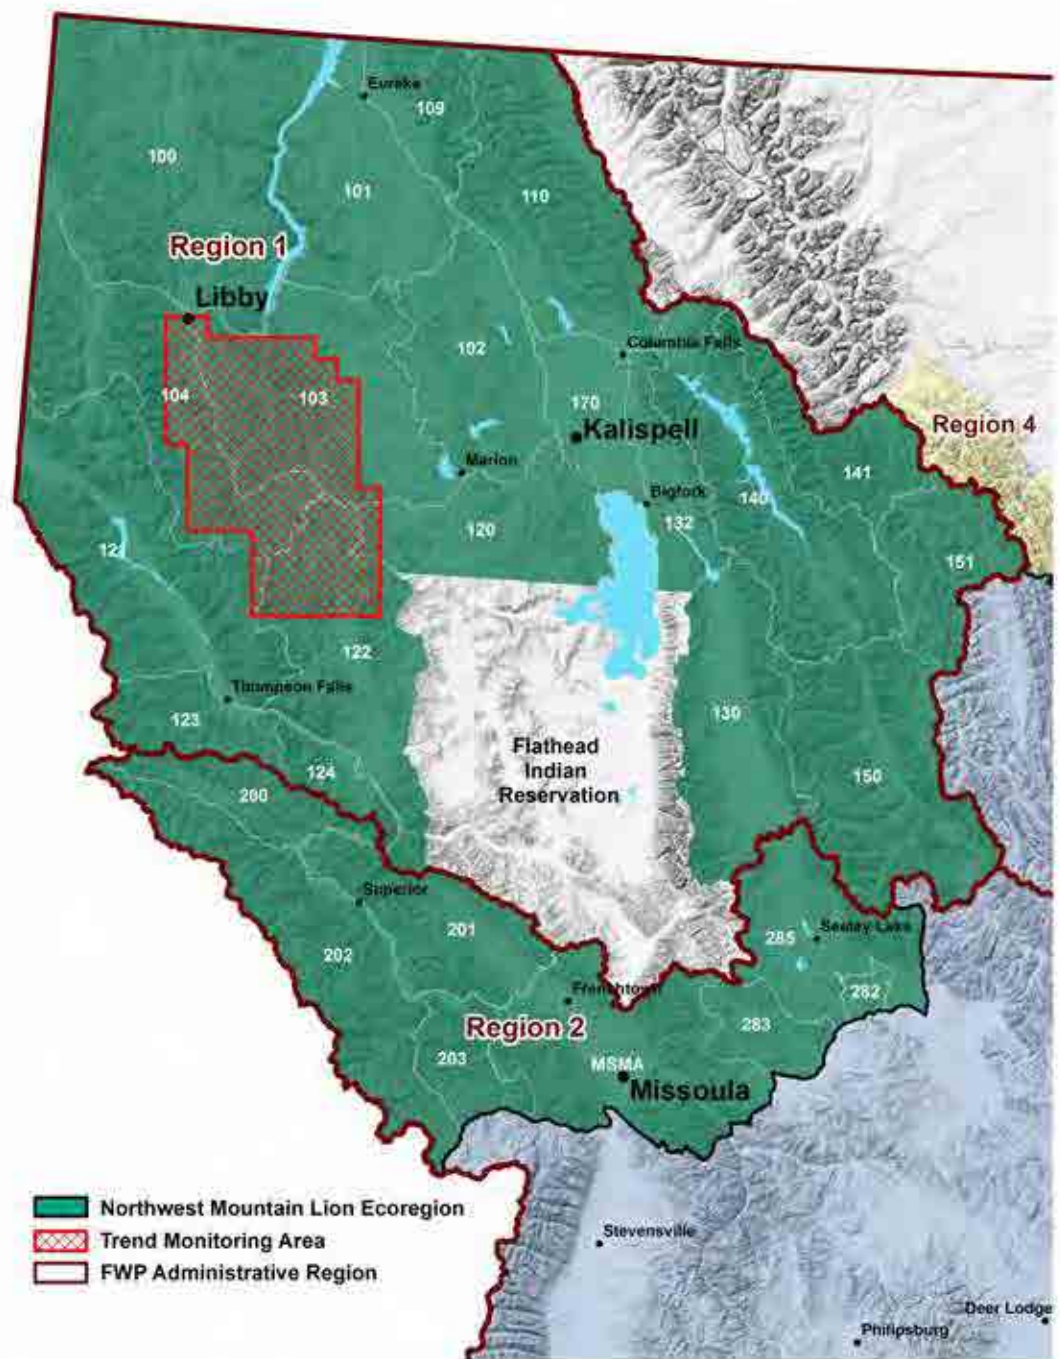

The Northwest mountain lion ecoregion encompasses all of FWP Region 1 (except for the Flathead Indian Reservation) and Region 2's northern Blackfoot and middle Clark Fork River drainages (Figure 10). It is Montana's smallest ecoregion at 36,893 km² but it contains the state's most continuous and highest quality lion habitat (average LMU RSF value = 0.83). Forests cover more than 90% of the Northwest ecoregion due to its Pacific maritime climate and moderate elevations.

Most of this ecoregion's lion habitat is either public land or publicly accessible private land. Hunter access during winter is extensive outside of designated wilderness areas. Tracking snow is generally present throughout the Winter Season.

The 2,550 km² Northwest mountain lion ecoregion Trend Monitoring Area includes the Libby Cr., Thompson River, and Fisher River drainages southeast of Libby. (Figure 11).

Mountain lion harvest in the Northwest ecoregion steadily increased during the 1990s, reaching a historic high of 344 (57% females) in 1998 (Fig 12). White-tailed deer make up as much as 90% of mountain lion prey in northwest Montana (Kunkel 1999, Montana Fish, Wildlife & Parks 2006). The ecoregion's white-tailed deer numbers were high in the mid-1990s before

Figure 10. The Northwest mountain lion ecoregion, trend monitoring area, and 2016 FWP hunting districts.

the severe 1996-97 winter significantly reduced this prey base. Lion harvest density, especially of females, was low during the 2000s but increased through the mid-2010s to approximately 4.6 lions per 1,000 km² (42% female), less than half the harvest density observed in the late 1990s.

Figure 11. The Northwest mountain lion ecoregion trend monitoring area divided into a grid of 102 5x5 km sampling cells.

Figure 12. Northwest ecoregion mountain lion harvest, 1990 – 2015.

West-central Ecoregion

The 51,665 km² West-central ecoregion includes the forested mountain ranges and intermountain valleys of the Bitterroot, southern Blackfoot, and upper Clark Fork watersheds west of the Continental Divide and the Rocky Mountain Front, Helena/Boulder valleys, Belt and Snowy Mountains to the east (Figure 13). The ecoregion includes portions of FWP Regions 2, 3 and 4.

Forests across the ecoregion are diverse and often separated by broad intermountain valleys. The average mountain lion habitat quality (average LMU RSF value = 0.72) is generally lower than in northwest Montana because high-quality lion habitat is more intermittent. There is extensive and well distributed public recreational access to winter lion habitat, although some local private land refuges exist. Snow conditions annually vary within and between watersheds—a lack of adequate tracking snow occasionally limits winter lion harvest in some areas.

The ungulate prey base and density varies across the ecoregion. Although white-tailed deer are generally common, mule deer and elk make up a greater proportion of available ungulates than in northwest Montana.

The 2,200 km² West-central ecoregion's Trend Monitoring Area includes the upper Blackfoot and east Nevada Cr. Valleys west of the Continental Divide (Region 2) and the Canyon Creek/Little Prickly Pear drainages east of the Divide in Region 3 (Figure 14).

Mountain lion harvest in the West-central ecoregion climbed to a high of 294 lions (53% female) in 1998 (Figure 15). Hunter harvest, particularly of females, was significantly reduced in the 2000s following perceived population declines. By 2015, overall harvest density increased to 3.1 per 1,000 km², well below the nearly 6.0 per 1,000 km² in the late 1990s—specifically, the 2015 female harvest was one third of the 1998 peak.

Figure 13. The West-central mountain lion ecoregion, trend monitoring area, and 2016 FWP hunting districts.

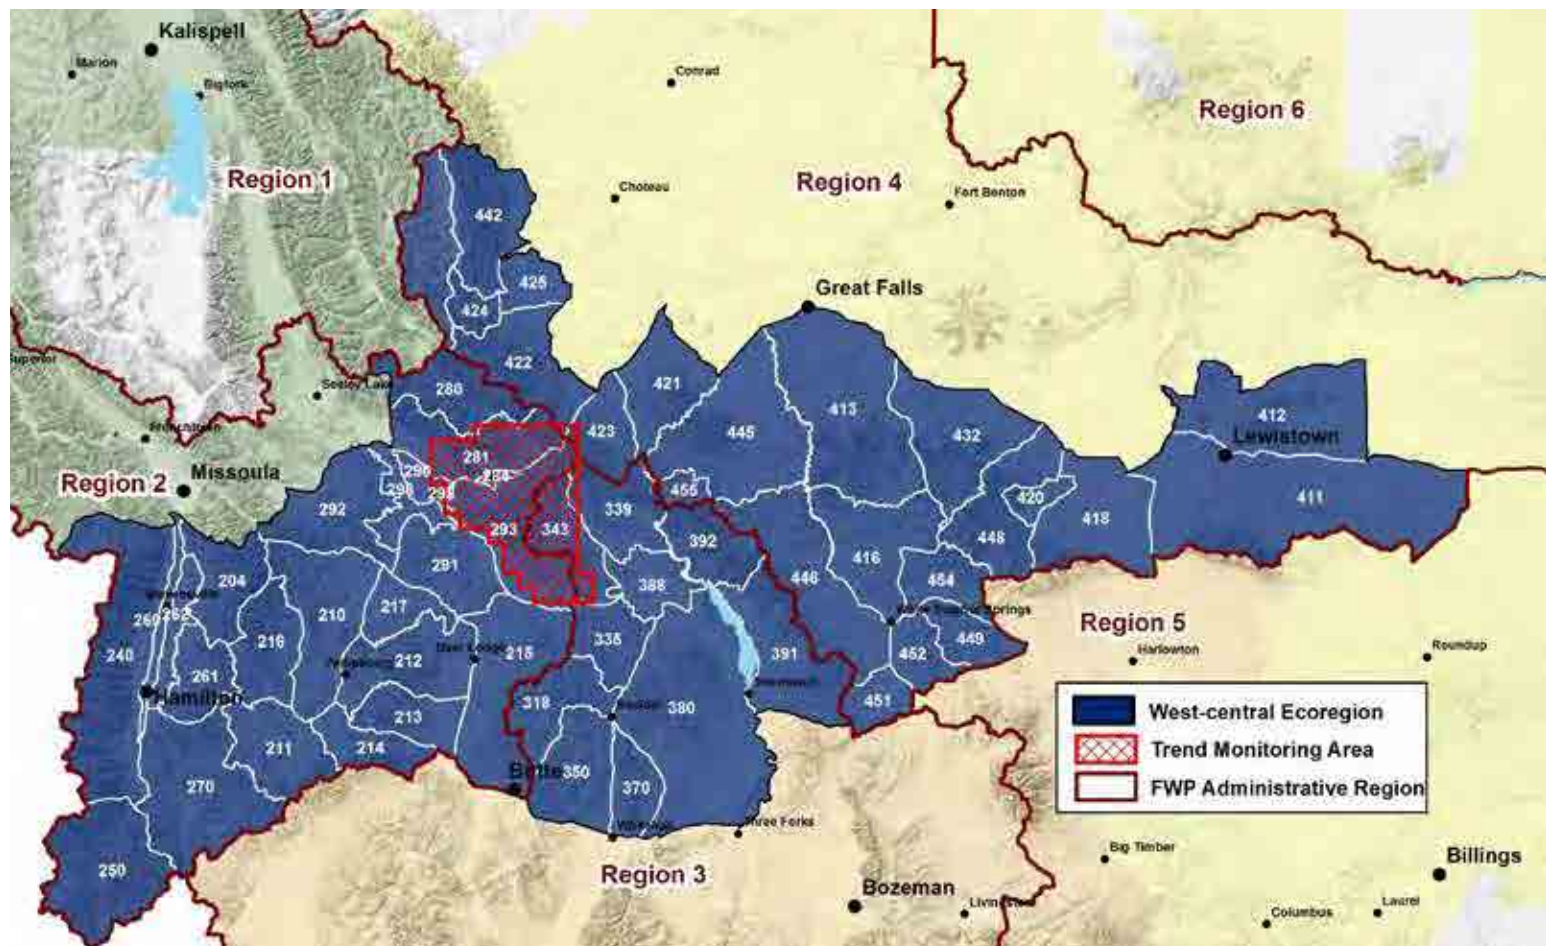

Figure 14. The West-central mountain lion ecoregion trend monitoring area divided into a grid of 101 5x5 km sampling cells.

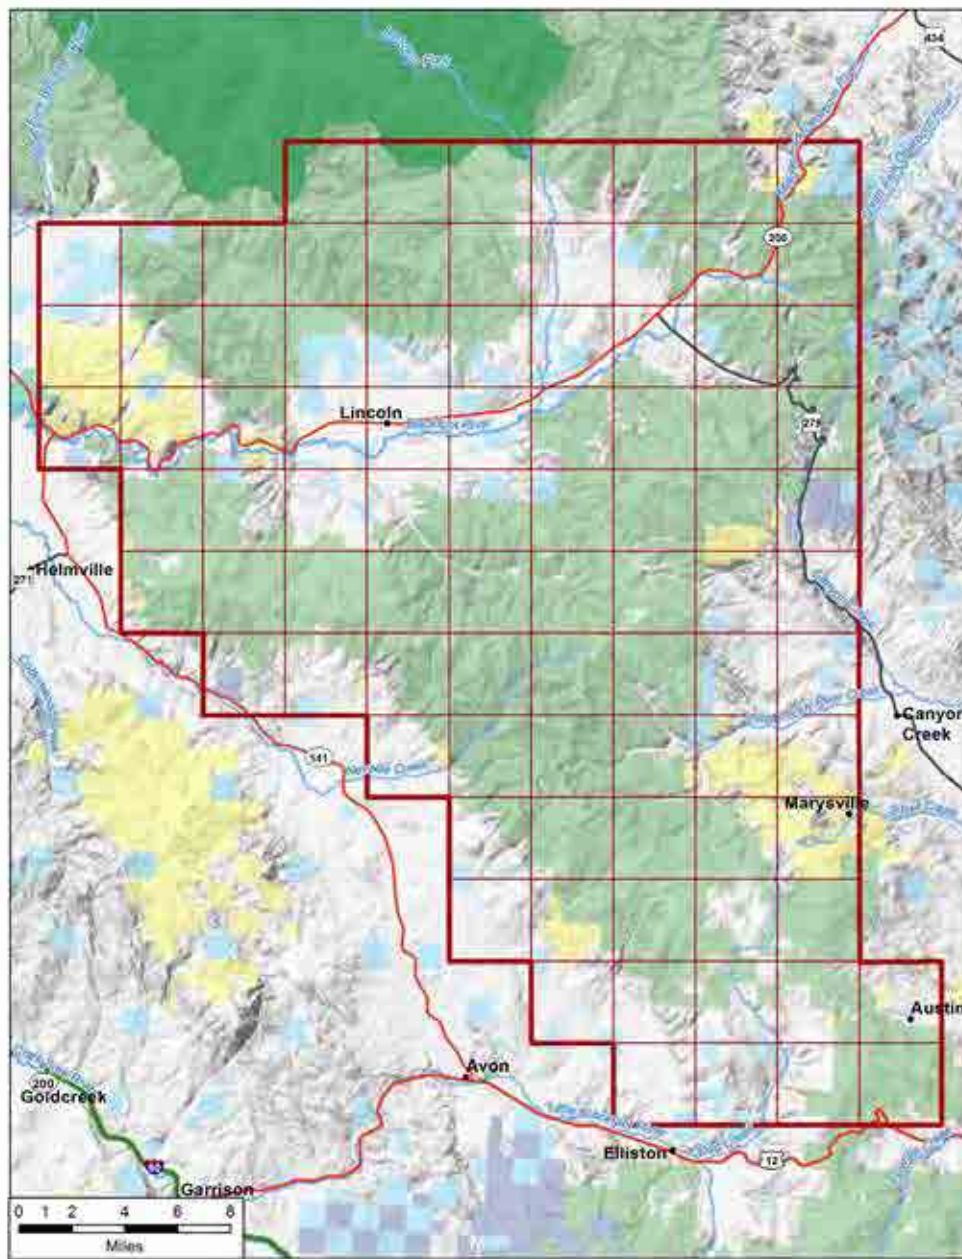

Fig. 15. West-central ecoregion mountain lion harvest, 1990 - 2015.

Southwest Ecoregion

Mountain lion habitat is relatively patchy and linearly distributed in much of the 52,487 km² Southwest ecoregion. This area extends from the Continental Divide and southwest Montana's island ranges, across the Greater Yellowstone Ecosystem to the Beartooths, Crazy Mountains, southeastern Little Belts, and southern Big Snowy Mountains. The ecoregion includes much of FWP Region 3 and western Region 5 (Figure 16). Although many portions of the ecoregion include high-quality lion habitat, only about a third of the total area is forested—the average LMU's RSF value in this ecoregion is 0.51.

Public access to winter mountain lion habitat is mixed; approximately 75% of lions harvested between 2007 and

2015 were taken on public land. Winter snow tracking conditions vary and can, at times, limit effective harvest.

The 2,525 km² Southwest ecoregion mountain lion Trend Monitoring Area is located in the Gallatin Range between Bozeman and Yellowstone National Park (Figure 17).

Total mountain lion harvest in this ecoregion peaked in the late 1990s, declined in the 2000s, then returned to near the 25-year average level by 2015. Much of this variation, however, was due to fluctuations in female lion harvest; male harvest has remained relatively constant since the mid-1990s (Fig. 18). Overall Southwest ecoregion harvest density was 1.75 lions per 1,000 km² in 2015.

Figure 16. The Southwest mountain lion ecoregion, trend monitoring area, and 2016 FWP hunting districts.

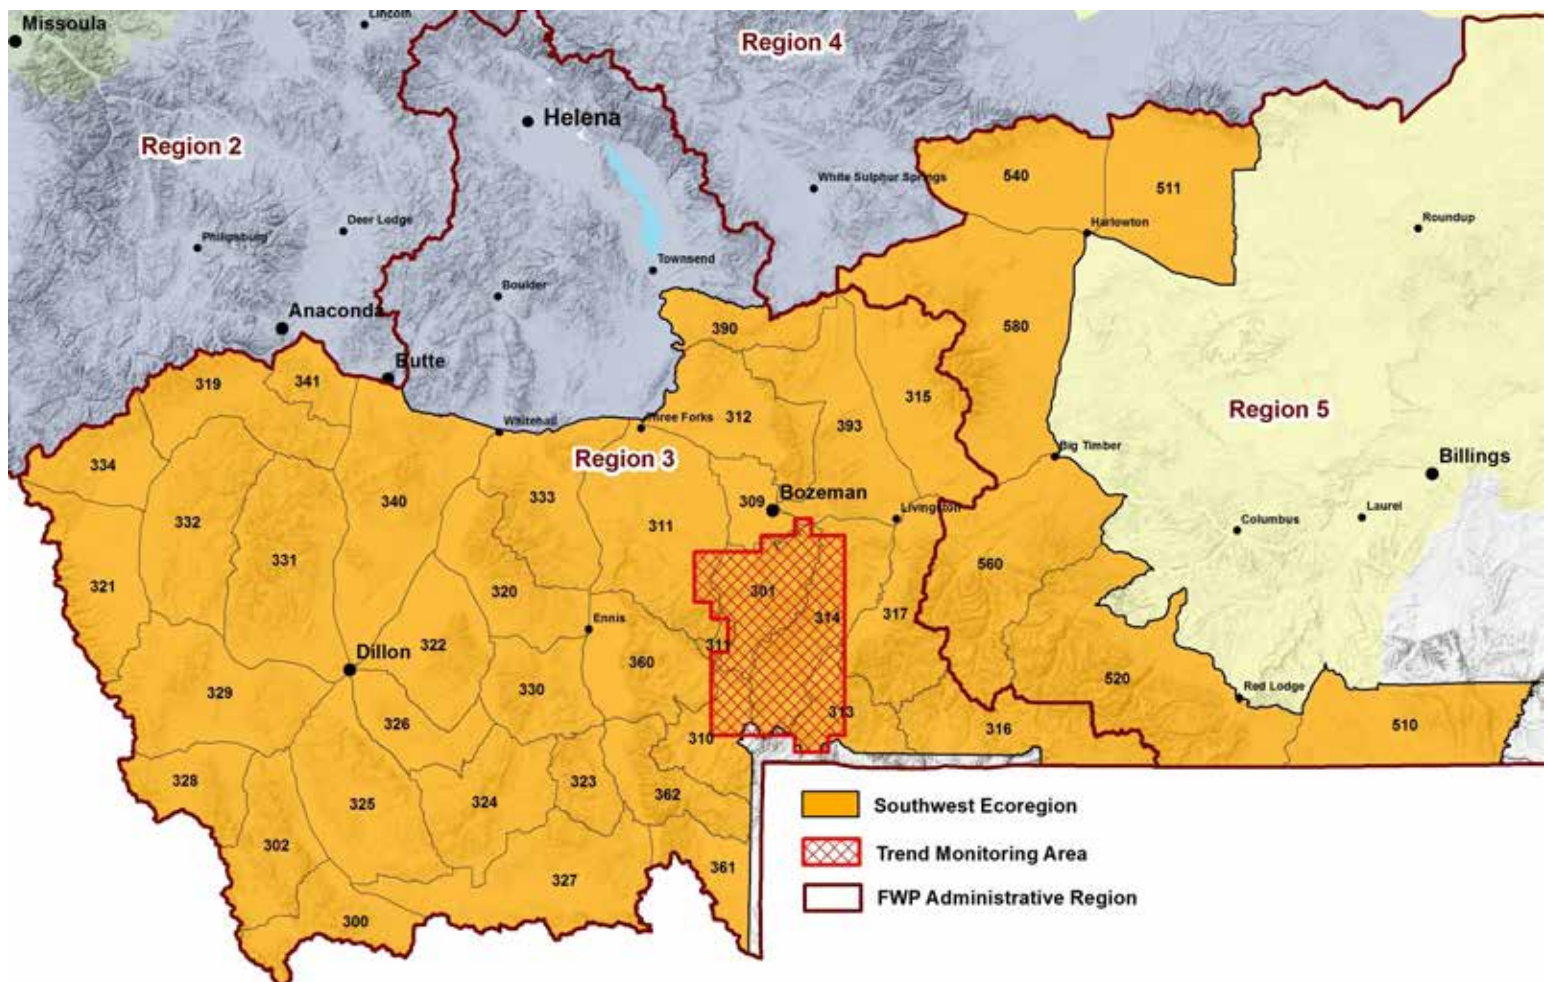

Figure 17. The Southwest mountain lion ecoregion trend monitoring area divided into a grid of 101 5x5 km sampling cells.

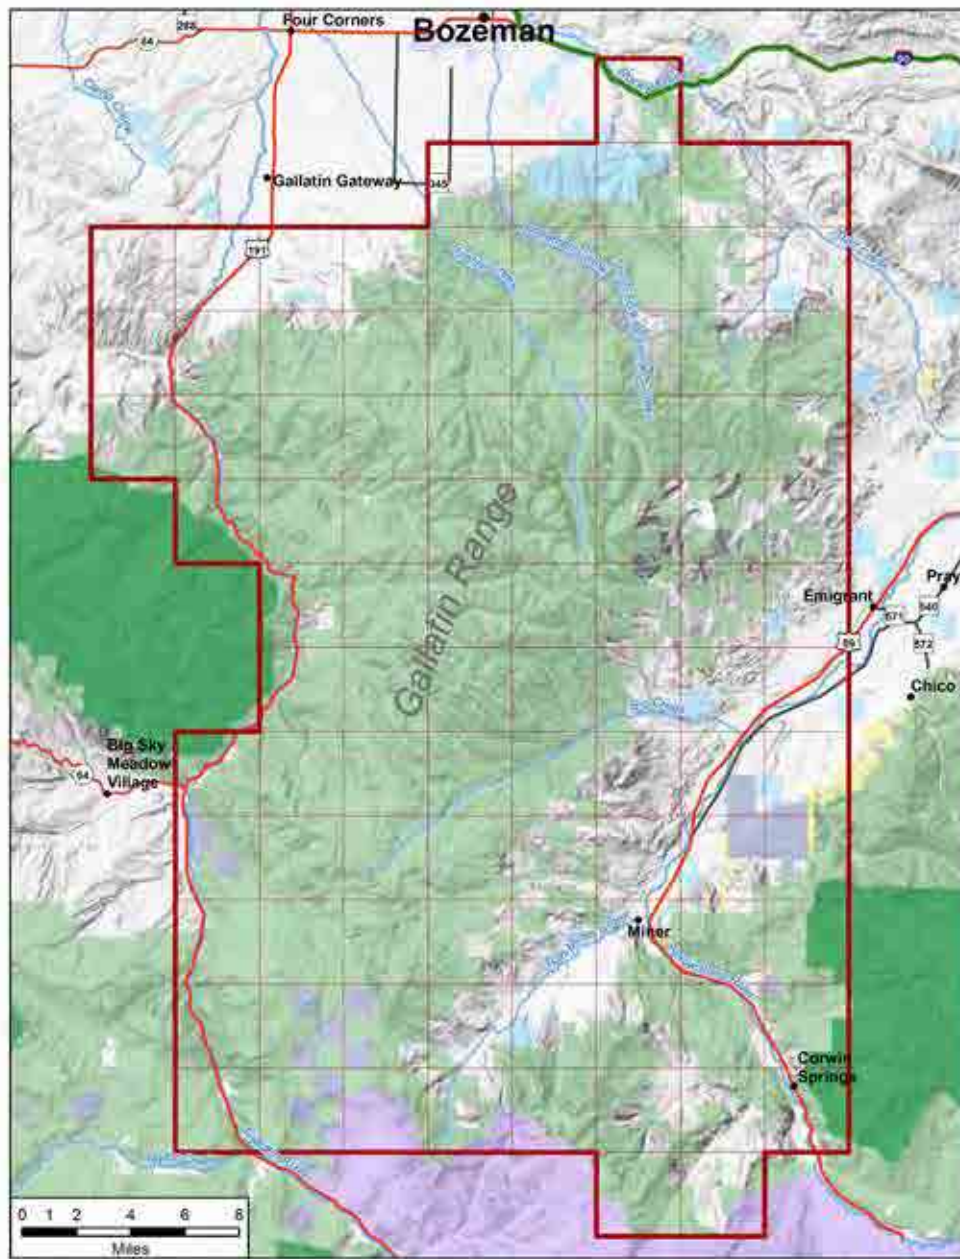

Fig. 18. Southwest ecoregion mountain lion harvest, 1990 – 2015.

Eastern Ecoregion

The 198,175 km² Eastern ecoregion is, by far, the largest in the state and includes all or portions of FWP Regions 4, 5, 6 and 7 (Fig 19). Much of the highest quality mountain lion habitat in eastern Montana lies within Indian reservations—FWP does not have routine mountain lion management jurisdiction on these reservations and they are excluded from the ecoregion for analysis and planning purposes. Less than 10% of the remaining ecoregion supports ponderosa pine or juniper-dominated forest. In general, patches of high-quality lion habitat are relatively small and widely distributed (average LMU RSF value = 0.38).

Genetic field monitoring data will not be routinely collected in the Eastern ecoregion and, therefore, no permanent Trend Monitoring Area has been designated. Lions in this ecoregion occur at an overall low density and sub-populations occur in discontinuous patches of suitable habitat. Inferences drawn from field sampling in one area would be of limited use for broad scale management of this ecoregion.

Mountain lion distribution and abundance has significantly increased in eastern Montana since the 1980s and recovery likely continued through the 2010s. Harvest has steadily increased since the 1990s (Fig. 20). Intermittent snow cover in eastern Montana can significantly reduce hound hunting's effectiveness. Therefore, in this ecoregion, quotas are more likely to serve as limits on harvest during years when snow conditions are favorable than as reliable annual harvest prescriptions.

Lion harvest in the Eastern ecoregion generally occurs in areas that the RSF describes as high-quality habitat on or near the Custer National Forest, Bureau of Land Management lands surrounding the Charles M. Russell National Wildlife Refuge, private land in the Bears Paw Mountains, in the Highwood Mountains, and along the northern Rocky Mountain Front.

CHAPTER 5

MONITORING MOUNTAIN LION ABUNDANCE

“The Holy Grail of cougar management has always been the question of ‘How many are there?’”

**Managing Cougars in North America—
J. A. Jenks, editor (2011)**

INTRODUCTION

To conserve mountain lions while ensuring sustainable recreational hunting opportunities, FWP needs accurate and up-to-date information about mountain lion population size and trend. In the past, managers used indirect measures of lion abundance, inferences drawn from long term field research projects, or anecdotal information about population status to inform decisions. Unfortunately, these sources of information often fail to accurately describe the effects of previous management actions and don’t allow us to precisely predict the effects of future harvest (Beausoleil et al. 2013).

Developing a method to obtain regular, accurate, extensive, and affordable estimates of the size of lion populations has been one of the highest priority mountain lion management needs (Beausoleil et al. 2008, Jenks 2011). Until recently, there was no cost effective and relatively quick way to produce reliable lion population estimates at a large enough scale to be meaningful for management (Choate et al. 2006, Beausoleil et al. 2016).

Many agencies that are charged with managing mountain lions rely on indirect measures, or indices, of lion abundance to make inferences about population changes because these indirect data are already available or relatively easy to collect. However, the actual relationship

FWP biologist preparing to fire biopsy dart to collect a genetic sample from a treed mountain lion, Western Montana, R. Wiesner

(if one exists) between a population index and true population size is rarely known and may be inconsistent over time (Anderson 2003).

When potential indices of abundance were formally compared to known populations, the indices often proved too insensitive to be useful management triggers. For example, Wolfe et al. (2015) found that although the number of lions treed-per-day, permit fill rate, and the proportion of females in harvest were correlated with abundance, those relationships were weak. These indices are also not generally relevant in Montana where most harvest is regulated by sex-specific quotas.

Although the sex and age of harvested lions can eventually indicate significant changes in a lion population’s size or

growth rate, these harvest indices are only able to detect relatively large and long term increases or declines (Stoner 2004, Anderson & Lindzey 2005, Robinson & DeSimone 2011).

In Montana, changes in harvest-age structure appear to broadly correspond to observed, long term, changes in lion abundance. When populations were thought to be high and growing during the early 1990s, a greater proportion of the harvest consisted of older lions (Table 6). Lion populations apparently declined during the early 2000s before recovering; both the average ages of harvested lions and the proportion of older lions in the harvest reflected this trend. A similar relationship was documented in western Montana's Garnet Mountains between 1997 and 2006 (Figure 21).

Statewide lion density declined and recovered dramatically between the mid-1990s and late 2000s. This pattern was, in part, driven by dramatic changes in statewide harvest rates that are unlikely to be applied in the future. The current magnitude of variation in statewide age-at-harvest is relatively small and annually variable. During periods when the amplitude of population change is moderate, trends in harvest-age are less informative.

Tracking changes in the ages of harvested animals may be somewhat useful where more direct measures of population trend are not available (such as eastern Montana), but the index is too insensitive to detect moderate, short term changes in an area's lion density. The proportion of older adult animals in harvest (especially females)

Table 6. Montana mountain lion age-in-harvest, 1988 – 2015.

	Female, Average Age	Male, Average Age	Combined, Average Age	% of Harvest > 5 Y.O.

2013	3.62	3.13	3.33	13.1
2014	3.34	3.35	3.34	11.0
2015	3.09	2.89	2.97	6.8

Figure 21. Minimum mountain lion population estimate, and mean adult (> 24 months) age of harvested lions, Garnet Mountains, MT (Robinson & DeSimone 2011)

Adult mountain lion leaving tracks in snow, D. Neils

is more strongly correlated with annual adult survival than is the overall mean or median age-in-harvest (Wolfe et al. 2015).

Relying on past years' harvest to inform future quotas is also problematic. This "sledgehammer approach" (Logan & Sweanor 2001) uses previous seasons' hunter success rates to determine future harvest quotas. Even if managers reduce harvest quotas as hunter success decreases, these incremental reductions may not match existing population levels and can lead to further declines. Harvest indices are also much less informative in jurisdictions, like Montana, where most harvest is limited by sex-specific quotas.

Patterns in total annual harvest or days required to fill an area's quota can be misleading when factors that are independent of mountain lion population trend most strongly predict year-to-year harvest. For example, in much of the Eastern ecoregion adequate tracking snow is present only sporadically— during winters when there is snow cover, harvest increases. In these cases, quotas effectively

prevent excessive harvest during years with favorable tracking conditions even though they will not be routinely met in other years.

Intensive winter track surveys, surveys of public lion observations, and hunter effort generally failed to detect known lion population changes quickly or before large changes in population size had already occurred (Beier & Cunningham 1996, Jenks 2011, Robinson & DeSimone 2011).

Long term capture and radio-telemetry studies were traditionally considered to be the most reliable way to estimate local lion populations (Cougar Management Guidelines Working Group 2005, Jenks 2011). This method requires researchers to attempt to capture and mark all resident individuals within a study area, account for additional unmarked animals, and then extrapolate observed and suspected home ranges across a study area to produce an estimate of abundance (Lambert et al. 2006, Cooley et al. 2009, Robinson et al. 2008 & 2014).

However, capturing, marking, and counting individual lions is impractical for routine lion population monitoring. Intensive capture and radio-tracking projects can take many years to complete, require significant field resources, and are prohibitively expensive (Hornocker & Negri 2009). The uncertainty around estimates developed using this field method is also often difficult, or impossible, to assess. Finally, this technique usually produces only minimum counts because all individuals in a study area are rarely captured and nonresident (transient) individuals are often either missed or discounted (Robinson et al. 2015).

Because it was so difficult to directly monitor mountain lion population size and trend at a large scale, some researchers suggested implementing “zone management” (Logan

& Sweanor 2001) or a similar “metapopulation model” (Laundre & Clark 2003) instead. These strategies advise maintaining large and well-distributed lightly hunted refuge areas (sources) that sustain more heavily-hunted areas (sinks) through emigration. Although metapopulation management doesn’t rely on accurate population estimates, it does require knowledge of immigration rates between heavily and lightly-hunted areas. Few studies have rigorously estimated these immigration rates and the metapopulation management model’s effectiveness remains largely untested.

Although several large patches of un- or lightly-hunted lion habitat (including national parks, wilderness areas, and Indian reservations) undoubtedly act as sources of

FWP biologists recover a DNA biopsy dart from treed mountain lion

lions that disperse to other areas in Montana (Robinson et al. 2015), these refuges are neither extensive or well distributed enough to subsidize unlimited harvest in the remainder of the state.

FWP will not further restrict lion harvest across broad areas of the state in order to create additional specific “source” areas and, therefore, does not intend to use the metapopulation model as the basis for its mountain lion Management Strategy.

Instead, FWP will manage for limited and sustainable mountain lion hunter-harvest opportunity on most lands within its jurisdiction. To enable this approach, FWP will periodically monitor the size and trend of lion populations in the Northwest, West-central and Southwest ecoregions. We will use rigorous, field-based techniques to estimate population size and trend, and we will remain open to incorporating new monitoring methods as they are developed and validated. Distributing this monitoring effort across these three biologically distinct ecoregions will reduce the uncertainty of the estimates developed using local monitoring data (Walters & Holling 1990, Conroy et al. 2012).

Subsequent Trend Monitoring Area abundance estimates can be directly compared to past estimates from the same area. Abundance estimates for the Trend and Supplemental Monitoring Areas (see Montana Mountain Lion Monitoring section, Chapter 5) can also be used to develop abundance estimates for their respective ecoregions. These periodic ecoregional estimates will allow managers to track changes in mountain lion abundance over time and will be included in the Integrated Population Model (Chapter 6) to predict the effect of future harvest prescriptions.

The same regular field monitoring will not be conducted in the Eastern ecoregion. There, lion subpopulations are patchily distributed and the ecoregion annually produces <15% of the state’s annual harvest. Other population indices and harvest management strategies will be used in this ecoregion to conserve hunted populations. However, Eastern ecoregion managers may choose to sample lion abundance in specific areas of interest to better understand local populations.

ESTIMATING MOUNTAIN LION POPULATIONS

Capture-recapture (CR) sampling has been a standard method used to estimate a population’s abundance for many years (Seber 1982). To produce a traditional CR estimate, some animals in a population are captured, marked, and released. Later, there is another capture effort and the number of marked animals within the second sample is counted. The proportion of the first sample detected in the subsequent sample is then used to calculate a population estimate.

Conventional CR sampling assumes that the effective sampling area’s size is known, that animals don’t enter or leave the study area, and that all animals have a similar probability of detection (Royle et al. 2013). Species like mountain lion that are wide-ranging, occur at low densities, and are difficult to detect violate these assumptions and may cause CR methods to produce misleading results.

SPATIAL CAPTURE-RECAPTURE

A newer spatial capture-recapture (SCR) method specifically addresses the shortcomings of traditional CR techniques when working with wide ranging, low-density species. SCR has been successfully used to estimate carnivore populations (Royle et al. 2011, Blanc et al. 2013) including mountain lions in Montana (Russell et al. 2012, Proffitt et al. 2015). SCR also works well with less invasive data collection techniques such as acquiring genetic samples from biopsy darts, hair, or scat.

Biopsy darts used to collect genetic samples from mountain lions

The SCR approach allows biologists to estimate population abundance within a defined area while also accounting for animals whose ranges partially or occasionally overlap the area surveyed. SCR methods consider the spatial organization of individual animals and the fact that the probability of an individual being recaptured decreases the farther that animal is from where it was originally detected or is known to reside. SCR methods also allow for sampling effort to vary across a study area when sampling wide ranging species (such as mountain lion) that use heterogeneous habitat.

Mountain lions in Montana prefer areas with habitat features such as forest cover, moderate slopes, forest edges, and intermediate elevations (Newby 2011, Robinson et al. 2015). Consequently, lions are not evenly distributed across different habitat types within an area. SCR methods use information about lion habitat preferences (specifically, the 2016 Montana mountain lion RSF) to inform estimates of population abundance.

Because estimated abundances are spatially explicit, population abundances associated with habitat of a certain quality within a sampling area can be extrapolated across broad landscapes as a function of that landscape's habitat quality. This allows information about lion abundance within Monitoring Areas to be used to estimate lion populations at the ecoregion scale.

SCR methods can also include information from harvested animals in population estimation models, thus allowing sampling to occur where hunter harvest is expected on and around the study area during the period the sampling is taking place (Efford 2014).

ABUNDANCE ESTIMATES

Monitoring an area's mountain lion abundance over time is essential to understanding the effect of hunter harvest on lion populations. However, variation in the ways researchers have defined their study areas, inconsistent reporting of age-classes included in population estimates, and the differences in estimation methodology make directly comparing lion densities reported in the literature nearly impossible (Hornocker & Negri 2009).

FWP will monitor and report the estimated winter density of all non-dependent individual lions—that is, lions that are legal to harvest—within an area

For example, researchers have variously reported densities of all mountain lions (including dependent kittens), the minimum number of resident adults, and the density of lions estimated across both seasonal and annual ranges. FWP will monitor and report the estimated winter density of all non-dependent individual lions—that is, lions that are legal to harvest—within an area.

In Montana, the average age that a young lion becomes independent of its mother is approximately 15 months (Robinson & DeSimone 2011). Montana law prohibits the harvest of young lions with body spots; these spots are nearly gone by 15 months of age (Currier 1983, Lindzey 1987).

Young lions make up a significant proportion of legal harvest. Of the known age lions legally harvested in Montana between 1988 and 2014, 42% were <3 years old and 15% were <2 years old. Many of these juveniles and subadults are transient, having yet to establish a fixed home range. The number of transient mountain lions in a population is difficult to quantify using traditional field sampling methods and this age class is often underrepresented in population estimates reported in the literature (Logan & Sweanor 2001).

Thus, an advantage of the SCR monitoring approach is that abundance estimates will include resident and transient animals, both of which are legal to harvest. The SCR method that FWP will initially use estimates the abundance of all independent aged lions within Trend Monitoring Areas and ecoregions during the winter monitoring period. Because all independent aged lions (including transients) are included, genetically based SCR abundance estimates may well be higher than estimates previously developed using other methods.

MONTANA MOUNTAIN LION MONITORING

FWP will use scientifically sound techniques to monitor Montana lion populations and produce periodic estimates of their size and trend. However, currently available monitoring techniques are both expensive and labor intensive. As field-based monitoring and analytical techniques improve and become more practical, FWP will remain open to incorporating them.

Initially, FWP will use the SCR sampling and analysis methods described by Proffitt et al. (2015) to periodically estimate independent aged mountain lion populations in the Northwest, West-central, and Southwest ecoregions. FWP has identified permanent Trend Monitoring Areas within each of these three western ecoregions which will be sampled on a rotating basis.

An additional Supplemental Monitoring Area within each ecoregion may also be sampled the year after the Trend Monitoring Area is sampled. Unlike the Trend Monitoring Areas, the location of Supplemental Monitoring Areas can change over time. These additional Monitoring Areas will allow FWP to sample a broader range of habitats within the ecoregions. Methods for selecting the permanent Trend and Supplemental Monitoring Areas, the field protocol for collecting data, and a description of the data analysis are included in Appendix 1.

Each new estimate of a Trend Monitoring Area's lion population can be directly compared to past estimates for that same area. In addition, the relationship between lion density and the 2016 RSF within an ecoregion's Trend Monitoring Area (sampled Year 1) and Supplemental Monitoring Area (sampled in subsequent years) can be

combined to develop an estimate of population abundance for the larger ecoregion. If, over time, pooling the two Monitoring Areas' data produces ecoregional estimates that are functionally similar to estimates calculated from using the Trend Monitoring Area data alone, continued sampling of Supplemental Monitoring Areas may not be necessary.

Finally, an ecoregion's population estimate will be input into the Mountain Lion Integrated Population Model (Chapter 6) to increase our understanding of past and predicted mountain lion population trend and to evaluate alternative harvest prescriptions. Uncertainty about mountain lion abundance impedes effective harvest management. More accurate abundance estimates will be used in an adaptive management framework to make management more predictable over time. The frequency of monitoring will affect the rate at which this uncertainty is reduced, but monitoring frequency will also depend on the availability of funding and other priorities.

Treed mountain lion, western Montana

CHAPTER 6

THE MONTANA MOUNTAIN LION INTEGRATED POPULATION MODEL

INTRODUCTION

Wildlife biologists use mathematical models to approximate the real ecological systems they manage. These models allow them to better understand how populations work and to make more accurate predictions about how they're likely to change in the future. The most useful models are built using rigorously collected field research data and have a clearly defined purpose. These data (such as the age a male lion will most likely disperse or an adult female's annual survival rate) describe what's most likely to occur as well as the range of probable outcomes we should expect. By combining the best information available about a species or system we can better understand them.

Dr. Paul M. Lukacs and Dr. Joshua Nowak of the University of Montana collaborated with FWP to develop the Montana Mountain Lion Integrated Population Model (IPM; Nowak et al. 2018). The IPM is a tool that combines available information about a mountain lion population (i.e. harvest, abundance, survival, and reproduction) into a single analysis of that population's demography. Managers can use the IPM to describe the effects of past management and make predictions about future population trends.

PREDICTING LION POPULATIONS USING THE IPM

The primary purpose of the IPM is to help wildlife managers, decision makers, and the public understand the effect of past and future harvest on mountain lion populations. The IPM is directly linked to the FWP lion harvest database, and a web interface allows users to input future possible harvest prescriptions (by sex and age class).

Using this information, the model forecasts the future population trend that would likely result from an

ecoregion's proposed harvest prescription. The output clearly shows the range and magnitude of the predictions' uncertainty for each year of the analysis; this uncertainty increases the further into the future the model is asked to make predictions.

Periodic abundance estimates that are developed from field-based monitoring (described in Chapter 5) can also be input into the model. These estimates make the IPM's predictions more precise. The IPM outputs the results of model runs as graphs (by population and by age and sex-class) as well as in a tabular format.

Montana's mountain lion IPM was built using the software program PopR which was developed in collaboration with Idaho Fish and Game, South Dakota Game, Fish and Parks and The University of Montana in 2014 (Nowak et al. 2018). PopR is a web based application linked directly to agency harvest databases through an interactive graphic user interface. It allows non-expert users to easily update data and change model parameters (such as assumed survival rates or reproduction) to evaluate the potential effects of future harvest levels. The IPM and web application were specifically designed to be repeatable, transparent, and easy for biologists to use.

The Montana mountain lion IPM can analyze populations within the three western Montana mountain lion ecoregions. Harvest data are input into and analyses are output by the IPM at the ecoregion scale.

**The Integrated
Population Model is a
tool that combines all
available information
into a single analysis of
mountain lion population
demographics**

The IPM contains two underlying model components: a biological process model and an observation model (Schaub & Abadi 2011). The biological process model describes what we know about lion population dynamics and vital rates (Caswell 2001). It uses parameters including age-class and sex-specific survival probabilities, fecundity by age-class, and estimates of overall population size (when those field estimates are periodically available). The observation model describes the data collection process and the link between field data, harvest records, and biological parameters.

Field-based estimates of population vital rates have some statistical uncertainty and fluctuate over time. That is, field data (i.e. litter size) occur as a distribution of observed values that produce both a point estimate and a range of likely values. The IPM combines and considers all sources of

uncertainty when predicting mountain lion population size and trend.

Field research has shown us that although many lion population vital rates (including reproduction and non-hunting survival) are remarkably consistent across the species' range, variability around average rates can significantly influence populations (Robinson et al. 2014). This variability is explicitly incorporated into the model and carried forward into predictions. The IPM allows users to estimate sex and age-specific population size and growth, as well as the precision of those predictions.

It's difficult to directly measure mountain lion vital rates and population trend frequently or extensively. Fortunately, lion ecology has been studied for decades in Montana and throughout the western U.S. The lion IPM allows for

a straightforward application of expert knowledge even when specific information about local or contemporary populations is sparse. The model generates reasonable estimates of those parameters managers cannot directly measure based on the range of values researchers have previously collected in the field.

The IPM uses Bayesian statistics that allow a range of possible but uncertain values to be substituted in lieu of new field data. The range of values can be ‘uninformative’ (allowing a wide range of values to be equally likely) or ‘informative’ (where values known to be more likely are given a higher probability). For example, the annual survival probability for mountain lions can take any value from 0 (certain to die) to 1 (certain to live). Field research suggests that annual adult female mountain lion survival is near 0.85 in the absence of harvest. Therefore, an uninformative range of values could be a uniform (0,1) while a more useful informative range of values would have a mean of 0.85 with a standard deviation based on the range of values reported in the research literature. Montana’s lion IPM uses informative values based on previous field research to improve model performance because it’s impossible to directly measure vital rates every place or every year.

MOUNTAIN LION IPM MULTI-STATE SURVIVAL MODEL

Long-lived species with moderate reproductive rates (like lions) are particularly sensitive to changes in survival rates (Gaillard et al. 1998). The chances of a lion surviving each year also changes as it grows older. Kitten survival is the lowest of any age-class. Field estimates of kitten survival are often biased high because dens are usually located sometime after birth occurs (eg. Robinson et al. 2014) and kitten deaths between birth and when researchers discover the den may not be accounted for. Juveniles and subadults typically experience higher mortality during transient and dispersal movements (Sweaner et al. 2000, Robinson et al. 2008). Once a lion establishes a home range, nonhunting mortality risk decreases until the lion reaches old age. Adult lions typically die from intraspecific strife and human caused sources like road kills, management removals, and sport hunting (Hornocker 1970, Logan et al. 1986, Cooley et al. 2009, Robinson et al. 2014).

The model generates reasonable estimates of parameters managers cannot directly measure based on the range of values researchers have previously collected in the field

Reported rates of lion survival vary and are plagued by small sample sizes (Hornocker & Negri 2009). The lion IPM default parameters are based on telemetry data from marked lions in Wyoming’s Teton Mountains (n = 100, 2001-2012), Washington’s Kettle Range (n = 36, 2002-2006) and studies in Montana’s Garnet Mountains and National Bison Range (combined n = 127, 1998-2006). These field data describe age and sex-class annual survival probabilities and error distributions used in the model (Appendix 2). Biologists can easily adjust input values if they have reason to believe that vital rates in their area are different from those observed during these field studies.

The IPM uses a known-fate multi-state survival model (Lebreton et al. 1992, Schaub et al. 2010, Servanty et al. 2010, Kery & Schaub 2011). The known fate assumption was necessary because the data included summaries of collar deployments but not true encounter histories. The IPM assumes that at the end of each month an animal could be in one of four states: a lion could be alive, dead by harvest, dead by other causes, or already dead at the beginning of that month. Animals whose fate was unknown because they left the area or whose collar failed are only included in the analysis up until the time they were last observed. Similarly, animals harvested outside Montana were only included up until they left the state so they did not contribute to Montana’s estimated harvest rates. A description of these specific biological inputs and assumptions is included in Appendix 2.

POPULATION RECONSTRUCTION

With the exception of kittens, Montana mountain lion reproduction and nonhunting mortality is not significantly affected by typical changes in harvest levels. That is, harvest doesn't reduce the probability of animals otherwise dying and changes in a population's harvest rates don't significantly affect the surviving individuals' fecundity. In much of Montana hunter harvest is the most likely cause of lion mortality. Research on hunted populations in

Montana's Garnet Mountains showed harvest to be largely additive to more consistent background nonhunting mortality risk (Robinson et al. 2014), and FWP is not aware of research results demonstrating that harvest of independent aged mountain lions is compensatory with other mortality sources. Because nonhunting mortality occurs at a relatively constant rate, the overall number of animals that die from nonhunting causes will vary with increases or decreases of the overall population.

FWP hound handler tracking a mountain lion to collect a genetic sample, western Montana

Hunter harvest can, and often does, affect lion population growth (Cooley et al. 2009, Hornocker & Negri 2009). Harvest data also gives managers information about past population numbers and sex/age composition in an area. When managers have reliable estimates of past and current population levels, they are better able to predict the effect of future harvest prescriptions on the lion populations they manage. The IPM uses survival estimates along with the annual harvest records to reconstruct past mountain lion populations (Gove et al. 2002, Conn et al. 2008). A description of these specific biological inputs and assumptions is included in Appendix 2.

If we have an estimate of the harvest mortality rate (from telemetry data) and know the number of lions harvested, dividing the number harvested by the harvest mortality rate gives us an estimate of the pre-hunt population size. This is then corrected for an "other mortality" rate, which is relatively constant.

"Population reconstruction" methods have been successfully used to estimate the size and trend of harvested fish and wildlife populations for over 70 years. The technique uses age-at-harvest, total harvest, harvest rate, and the rate of non-harvest mortality to "rebuild" the past population that must have existed in order to have produced the known type and level of harvest.

The IPM uses these age and sex-specific survival estimates (from field research studies) along with the annual harvest rate to reconstruct past mountain lion populations. Current hunter harvest by sex, age, and location (data that, in Montana, are collected during the mandatory lion harvest inspection) is input to the model after the close of the harvest season each year. By combining survival models with observed harvest data, the IPM estimates annual population size as well as a confidence interval around these estimates.

Direct, field-based estimates of population abundance may be input into the model when they are available. These periodic field estimates can significantly improve past and future population estimates for individual lion ecoregions.

MOUNTAIN LION REPRODUCTION INTEGRATED POPULATION MODEL INPUTS

Lions can begin reproducing as early as 17 months of age or as late as 3 years old (López-González & González-Romero 1998). Studies focused on modeling cougar population dynamics often assume females reproduce for the first time at 24 months (Robinson et al. 2008, 2014; Cooley et al. 2009); the IPM uses this same convention.

Lions are induced ovulators, they can conceive during any month of the year (Bonney et al. 1981, Robinson et al. 2014), and gestation lasts about 92 days (Logan & Sweeney 2001). Despite their ability to give birth year round, most researchers working in northern latitudes report a birth pulse in mid or late summer (Laundre & Hernandez 2007, Robinson et al. 2014). The IPM assumes a default birth date of July 1.

**Montana
mountain lion
reproduction
and non-hunting
mortality is not
significantly
affected by
typical changes
in harvest levels**

Intervals between subsequent births are a function of gestation length, kitten time to independence, and any lag that may exist between rearing and breeding. Previous population models have assumed a 24-month interbirth period (Robinson et al. 2008 & 2014, Cooley et al. 2009). Field researchers measuring interbirth intervals in the wild report a range of about 17 to 24-months between litters (Lindzey et al. 1994, Logan & Sweanor 2001, Hornocker & Negri 2009). Newborn kittens trail their mothers for 1 to 2 years before dispersing or achieving independence (Hornocker & Negri 2009). In the Garnet Mountains of Montana, Robinson et al. (2014) observed an average dispersal age of 15 months ($n = 33$, range: 11-23 months), similar to that observed by others (Sweanor et al. 2000; Logan & Sweanor 2001). The IPM uses an interbirth interval of 24 months as the model default.

Mountain lion litter sizes are remarkably similar across a wide range of locations and conditions. A common estimate of litter size is 3 kittens (Spreadbury et al. 1996, Logan & Sweanor 2001, Robinson et al. 2014). Litter size does not appear to vary with harvest intensity, but may fluctuate with prey density (Wilson et al. 2004, Stoner et al. 2006, Robinson et al. 2014). The IPM uses the estimate of an average of 2.92 kittens per litter derived from recent research in Montana's Garnet Mountains (Robinson et al. 2014; $n = 24$ litters) and it assumes that half of the kittens are female. Throughout the model, the average and range of litter sizes observed in the Garnet study

is used to describe a normal distribution of litter sizes truncated between 0 and 3. The model also assumes that litter size remains constant through time and does not fluctuate with population size, prey density, or the female's age. A description of the specific biological inputs and assumptions used is included in Appendix 2.

USER CONTROLS

Biologists can adjust most model inputs such as biological assumptions, future harvest prescriptions, and model controls. The default biological assumptions are based on field research data and should only be changed if users believe that future or local circumstances have changed lion reproduction or non-harvest survival.

Users can easily use sliding scales provided on the user interface to change future harvest prescriptions by sex and to allow the model to estimate the effects of those changes. Users only need to input total anticipated hunting mortality by sex—the model will assign future harvest mortality to age classes that are consistent with the distribution of previously observed harvest ages. If the user believes that the harvest-age distribution will be different than past years, a different distribution can be manually assigned.

For more information on the model controls and settings, including the IPM model's computer code in programming language R, see Appendices 2 and 7.

CHAPTER 7

MOUNTAIN LION HARVEST REGULATION

REGULATION HISTORY

Montana's mountain lion hunting regulations became increasingly complex, and inconsistent, during the 45 years since lions were designated as a big game species. New and modified regulations were adopted in an ad hoc fashion as various Fish and Wildlife Commissions struggled to address public concerns about harvest levels, prey populations, harvest distribution, parity between hound handlers and hunters without dogs, nonresident and outfitter participation, human-lion conflicts, and scores of other issues.

In FWP regions where hunting was allowed, mountain lion harvest was not restricted by quotas or limited licenses until the mid-1980s. Hunters were simply required to purchase a license and allow FWP personnel to inspect lions following harvest. By 1988, most FWP regions had established Lion Management Units with individual harvest quotas (and/or female subquotas) to limit harvest. The Department began to require harvested lions to be reported to a hotline within 48 hours and presented for physical inspection within 10 days. The reporting period was reduced to 12 hours in subsequent seasons.

Until 1997, most Winter lion hunting seasons ran from 12/1 to 2/15, after which hound handlers could continue to pursue lions with dogs during dedicated “chase” or “training seasons” that extended into April. More recently, hound training seasons open 12/2 and run concurrent with established harvest seasons.

Montana lion populations appeared to significantly expand and grow after 1980, as did the popularity of recreational hound hunting. Both resident and nonresident hunter participation increased to historically high levels by the mid-1990s (Figure 22) and the number of nonresident hunters was not limited. During that period, conflicts between resident hound handlers, nonresident hunters, and outfitters were common in portions of northwest and west-

central Montana where winter snow is consistently present and there is plentiful access to public land lion habitat. For example, In Region 1 approximately half of harvested mountain lions were taken by outfitted or nonresident hunters during the 1990s—guided hunter harvest often closed LMUs before local “weekend” hunters had an opportunity to hunt. Similarly, over 30% of successful hunters in Region 2 were nonresidents during the 1990s; this proportion rose to 47% by 2005.

In 2000, FWP's Region 1 began to issue resident mountain lion hunting permits which, in effect, limited nonresident hunters' opportunity. Beginning in 2005, most Region 1 LMUs were managed using limited Special Mountain Lion Licenses that restricted nonresidents to no more than 10% of the licenses offered in a drawing.

Montana's mountain lion hunting regulations became increasingly complex, and inconsistent, during the 45 years since lions were designated as a big game species

Similarly, in 2006, Region 2 began to require that nonresidents draw a Special Mountain Lion License to harvest a lion in most of the region. Resident lion harvest was managed using a quota and nonresident Special License numbers could not exceed 10% of an LMU's total quota. The Fish and Wildlife Commission required that both resident and nonresident hunters draw a Special Mountain Lion License in most Region 2 LMUs beginning in 2008.

In Region 2, managers were not able to achieve predictable harvest using only these Special Mountain Lion Licenses. License fill rates varied widely from year-to-year and across LMUs. Female lion harvest was also virtually eliminated despite rapidly increasing populations. Therefore, in 2012,

Figure 22. Montana mountain lion license sales, 1973 – 2015.

Region 2 introduced an additional Late Winter Season (opening 2/1) during which hunters with a General Lion License could hunt until any quotas previously unfilled by Special Mountain License holders were met (this became known as a “hybrid” season). Nonresident participation was unlimited during the Late Winter Season and nonresident harvest rates more than doubled after the Late Winter Season was adopted.

Regions 3-7 continued to limit harvest during this period using sex-specific quotas and subquotas. Conflict between resident and nonresident hunters in these regions was low and the Fish and Wildlife Commission did not impose restrictions on nonresident harvest opportunity in these Regions.

Prior to 1997, all legal harvest occurred during the Winter Season (that immediately followed the 5-week fall General Deer/Elk season) during which hunting with the aid of dogs was allowed. Beginning that year, portions of the state began to also allow lion harvest during the fall General

Deer/Elk Season but without the use of dogs—fall seasons were adopted statewide in 1999. In 2010, the Commission added a statewide Archery Only Season that corresponded with the Archery Only Deer/Elk Season.

The Commission responded to concerns that Fall Season harvest could significantly reduce winter hound harvest opportunity by adopting separate LMU harvest quotas for the combined Archery Only and Fall Seasons. In most cases, if harvest prior to the Winter Season(s) exceeded 20% of a lion management unit’s total quota or number of Special Lion Licenses, that LMU’s Fall Season would be closed.

The separate quota for Archery Only and Fall Season harvest added complexity to the regulations but did not appear to meaningfully affect the seasonal distribution of lion harvest. Between 2007 and 2016, 95% of all hunter harvested lions in Montana were taken during the Winter Seasons with the aid of dogs. During that same period 11% of the state’s LMUs were closed during any given Archery

Only or Fall Season due to the 20% quota being met and 85% of those LMUs had an Archery Only/Fall quota equal to only one lion. Harvest that met fall quotas in these LMUs occurred a median of 16 days from the end of the 85-day Archery Only/Fall Season. The Archery Only/Fall Season quota was unlikely to reduce overall harvest in LMUs because that harvest was deducted from the LMU's quota and subquota.

However, harvest during the fall seasons is additive to prescribed Winter Season harvest in LMUs where the number of Special Mountain Lion Licenses issued serves as the effective harvest limit. Because of this difference, maintaining a separate Archery Only/Fall Season harvest quota may be necessary in LMUs where harvest is managed using Special Mountain Lion Licenses, instead of quotas.

HARVEST SEASON SETTING

This Strategy identifies four mountain lion ecoregions within the state that will be the basis for both monitoring populations and establishing broad harvest objectives. Within an ecoregion, FWP managers will work with the public and the Fish and Wildlife Commission to:

1. Develop clear and measurable population, harvest, and hunter opportunity objectives for the ecoregion.
2. Determine an overall harvest prescription that is likely to achieve the ecoregion's explicit population objectives.
3. Distribute harvest opportunity across the ecoregions' LMUs to address local concerns, reduce hunter crowding, and to focus or limit harvest where necessary.
4. Actively monitor the effect of the harvest prescription over time.
5. Adjust management objectives and harvest prescriptions, as necessary.

This process is described, in detail, in Chapter 8.

The amount of harvest that occurs in any one LMU matters much less to an ecoregion's mountain lion population than the overall harvest within that LMU's ecoregion. That is, whether an individual LMU's harvest limit (or quota) is reached or exceeded during a given year (due to weather, hunter participation, or other factors) is less important than the total annual ecoregional harvest.

Managers may intentionally recommend a relatively high harvest rate in certain LMUs (e.g. those including urban areas) or relatively low harvest rate in others (where access is challenging or tolerance for lions is high). As long as harvest is generally distributed across an ecoregion, the sum total of harvest is what will affect the ecoregion's population status and trend.

Therefore, in an LMU where harvest is limited by a quota, that quota will simply serve as "trigger" to initiate the closing of the LMU to further harvest. A quota is not necessarily a harvest objective for the LMU. When setting LMU quotas, biologists will anticipate how much additional harvest (if any) is likely to occur between the time the LMU's Season closure is publicly noticed and when the closure is effective. Subsequent ecoregional harvest decisions will consider the actual harvest that occurred in previous years' Seasons. Individual LMU quota "over runs" or "under runs" will be fully accounted for in future management decisions.

From a population standpoint, harvest that occurs in any one LMU matters much less than the overall level of harvest within that LMU's ecoregion

In LMUs managed using Special Mountain Lion Licenses, an area's average Special License fill rate (by sex) will be used to determine the overall number of licenses that should be offered to meet the ecoregion's harvest objective. Any differences between projected and observed Special License fill rates will be considered when determining future license levels. As with General License areas, decisions about future harvest prescriptions will be based on the modeled and measured effect the actual past harvest had on ecoregional populations.

There is little biological justification to frequently adjust mountain lion harvest prescriptions. Large scale mountain lion populations are very resilient to moderate changes in harvest and updated population estimates (both within trend areas and for the western ecoregions) will be available only periodically. Therefore, although FWP will routinely consider changes to mountain lion hunting season structure and quota levels, actual adjustments could be made less frequently.

LEGAL AUTHORITY

The Montana Fish and Wildlife Commission has statutory authority to regulate the management of wildlife (87-1-201), specifically "Large Predators" (87-1-217), including mountain lions. The Commission may determine seasons, bag limits, possession limits, and means of take for mountain lions as it deems appropriate (87-1-304). Montana statute describes specific resident and nonresident licenses required to hunt mountain lions (87-2-507, 508) and the license necessary for residents to pursue lions with dogs during the Training Season (87-2-521). Montana law limits hunters to taking no more than one mountain lion per license year (87-2-702) and allows the use of dogs to hunt or capture mountain lions during designated seasons (87-6-404). It is legal to kill a mountain lion at any time that is attacking, killing, or threatening to kill a person or livestock (87-6-106), using dogs if necessary (87-3-127).

Consistent with Montana law and Administrative Rules, when the Commission decides that it's necessary to limit nonresident harvest opportunity

Montana law specifically allows the Commission broad discretion to regulate the allocation of hunting opportunity among resident and nonresident hunters:

87-1-301. Powers Of Commission

(6) (a) The commission may adopt rules to:

- (i) limit the number of nonresident mountain lion hunters in designated hunting districts; and***
- (ii) determine the conditions under which nonresidents may hunt mountain lion in designated hunting districts***

(b) The commission shall consider, but is not limited to consideration of, the following factors:

- (i) harvest of lions by resident and nonresident hunters;***
- (ii) history of quota overruns;***
- (iii) composition, including age and sex, of the lion harvest;***
- (iv) historical outfitter use;***
- (v) conflicts among hunter groups;***
- (vi) availability of public and private lands; and;***
- (vii) whether restrictions on nonresident hunters are more appropriate than restrictions on all hunters.***

under the above statute, nonresident licenses will be limited to numbers not exceeding 10% of the total licenses or quotas assigned to a given hunting area (87-2-506, 12.3.105). LMUs with a quota (or number of licenses) of less than 10 will be combined with similar Regional LMUs and a number of nonresident licenses, not exceeding 10% of the combined total quota(s), will be allocated among those districts on a rotating basis (as described in ARM 12.3.116)

MODEL HARVEST REGULATIONS

Following are the three mountain lion hunting season structure alternatives Montana will use to manage hunter harvest. Managers may select an LMU's Season Type from among these three alternatives to consistently address the diversity of management challenges and needs across the state while minimizing regulation complexity. In most cases, changes to an individual LMU's season structure and/or quota(s) will be considered every second year.

Season Type 1:

Special Mountain Lion License LMU

MCA 87-1-304(e) allows the Fish and Wildlife Commission to issue limited Resident (Class D-2) and Nonresident (Class D-1) Special Mountain Lion Licenses. These licenses are valid in a single LMU and hunters can harvest a mountain lion only in that LMU during the Winter Season. FWP offers a limited number of these Special Licenses each season. Therefore, they are allocated by a random drawing and nonresident hunters are limited to

no more than 10% of the total number of available licenses (87-1-301). Sex-specific licenses or subquotas may also be designated to help achieve harvest objectives. Once a subquota is met (and the season for that sex closes), Special License holders may continue to hunt for lions of the remaining sex through the end of the legal harvest season. Both Special License holders and General License holders may harvest a lion during the Archery Only and Fall Season Without Dogs in these LMUs, but that harvest will be subtracted from any sex-specific subquotas for that LMU. Managers may choose to implement a combined Archery Only/Fall Season quota or subquota where necessary.

Season Type 2:

General License LMU

Hunters possessing a General License may harvest a mountain lion during the Archery Only, Fall Season Without Dogs, or Winter Seasons until the total or sex-specific quota for that LMU is met. There is no additional limit to nonresident opportunity to harvest a mountain lion using this Season Type.

Season Type 3:

Resident General License, Nonresident Special Mountain Lion License LMU

Resident hunters possessing a General License may harvest a mountain lion during the Archery Only, Fall Season Without Dogs, or Winter Seasons until the total or sex-specific quota for that LMU is filled. Nonresident hunters must apply for, and receive, a LMU-specific Special Mountain Lion License to harvest a mountain lion in that LMU during the Archery Only, Fall Season Without Dogs or Winter Season. Special Mountain Lion Licenses will be offered to nonresident applicants in quantities not exceeding 10% of the LMUs total combined harvest quota(s). LMUs with a total quota of less than 10 will be combined with similar Regional LMUs and a number of nonresident licenses, not exceeding 10% of the combined total quota(s) for those LMUs, will be allocated among those LMUs on a rotating basis (as described in ARM 12.3.116).

CHAPTER 8

ADAPTIVE HARVEST MANAGEMENT

This Strategy will provide FWP and the public with more accurate information about Montana's current, and likely future, mountain lion populations. However, there will always be some uncertainty about the precise effects of our management actions on lion populations. Although the overriding Conservation and Management Guidelines that direct Montana's mountain lion management decisions will

not change, specific local management objectives may well need to be refined over time as more information becomes available and conditions change.

In this chapter, we describe the adaptive harvest management process FWP will use to develop, evaluate, and adjust specific mountain lion management actions. This process relies on field monitoring and population modeling data (described earlier in this Strategy) to measure the results of management actions against explicit objectives that the public, FWP, and the Fish and Wildlife Commission collaboratively develop.

FWP hound handler collects genetic sample during mountain lion SCR monitoring in western Montana's Region 2.

**Adaptive management
can help reduce
decision-making gridlock
by making it clear that
decisions are provisional,
their effects will be
carefully monitored, and
that modifications are
expected**

Adaptive management is a science based approach to decision making that's useful when there is uncertainty about a decision's outcome. It is a cycle of planning for an action, doing the action, measuring what happened, and then modifying the next action (if needed) based on what you learned. The basic principles of adaptive management have been used for centuries (Falaruw 1984) and are increasingly employed by natural resource management agencies, including FWP (Montana Fish, Wildlife and Parks 2001).

The process works to continually improve our understanding of a system by comparing the resource's actual versus predicted response to management treatments (Nichols & Williams 2006, Williams et al. 2007). Adaptive management emphasizes 'learning while doing' and then adjusting management based on what was learned (Walters & Holling 1990). It is specifically not 'trial and error'— instead, managers explore alternative ways to meet management objectives, predict the outcomes of those alternatives based on the current state of knowledge, implement one or more alternatives, monitor the impacts of the management actions, and then use the results to adjust management actions as needed to more effectively meet objectives. Over time, resource management improves while uncertainty is reduced.

An adaptive management system requires the following conditions (Williams & Brown 2012):

- Resources are responsive to management but actual outcomes are uncertain;
- Management objectives are clear and measurable;
- There is both a range of management alternatives and the flexibility to change prescriptions as understanding improves over time;
- Monitoring can effectively describe the effect of the management action;
- There is a sustained commitment to the process by both stakeholders and decision makers.

Resource models are a critical component of the adaptive management approach. Models allow managers to use the most current information to predict the effect of possible treatments. They also represent what we don't yet know about how the system works—these uncertainties are explicitly incorporated into the model. The credibility of predictive models can improve through time as new information becomes available and uncertainty is reduced.

The effects of management actions must also be monitored so that the actual response can be compared to what was initially predicted. A successful monitoring program provides data that specifically describes the effects of the management action. Monitoring efforts must be designed from the start with that goal in mind (Szaro et al. 1999, Nichols and Williams 2006).

Disagreement about the past, and potential, effects of management decisions often leads to conflict among stakeholders. Adaptive management can help reduce decision making gridlock by making it clear that decisions are provisional, that their effects will be carefully monitored, and that modifications are expected. Management itself allows us to learn about, and therefore better manage, the resource through time.

Stakeholders and managers work collaboratively to develop mountain lion harvest regulations in Region 2 (2012).

MONTANA'S ADAPTIVE MOUNTAIN LION HARVEST MANAGEMENT PROGRAM

An adaptive harvest management process will guide most of Montana's mountain lion harvest decisions. FWP will use the best available science to develop the modeling and monitoring methods necessary to fully implement this Strategy. The modeling and monitoring techniques described in this document will be periodically reviewed and updated to ensure that we continue to use the most rigorous and up-to-date scientific methods practically available.

FWP used a habitat model (Chapter 3) to describe four distinct and biologically meaningful mountain

lion "ecoregions" within the state (Chapter 4). These ecoregions will be the spatial basis of FWP's lion monitoring program. FWP will work with stakeholders to periodically develop measurable mountain lion management objectives for each of these ecoregions. These objectives will be periodically reviewed, and potentially refined, by FWP and the public.

The likely effects of alternative harvest prescriptions will be evaluated using an Integrated Population Model (Chapter 6). These predictions will help stakeholders and FWP recommend an alternative to the Fish and Wildlife Commission that is most likely to meet that ecoregion's objectives.

In most cases, management alternatives will include an overall harvest prescription for each ecoregion. Harvest opportunity will then be allocated among the ecoregions' individual lion management units to distribute hunter effort and address local issues.

FWP will use field data to periodically estimate mountain lion population size, composition, and trend within the Northwest, West-central, and Southwest ecoregions (Chapter 5). These periodic population estimates will be used to improve the IPM's predictions, to assess how well management objectives are being met, and to inform decisions about future harvest prescriptions.

Other monitoring data including hunter effort and success, location and age of harvested animals, conflict rates, and prey status will be collected annually throughout the state. These additional data will be considered when evaluating management alternatives. Harvest data, weather, patterns of conflict, harvest success and other metrics will be the primary data used to guide management in the Eastern ecoregion.

The adaptive management approach includes the following basic steps (Figure 23):

Step 1 – Involve stakeholders

Stakeholders (including the public, managers, and decision makers) help design an adaptive management program, set management objectives, and develop management actions. Stakeholders must be committed to the adaptive management process for the long term.

FWP biologists and managers routinely meet with hound handlers, other hunters, and mountain lion advocates to share data and solicit public input concerning ongoing mountain lion management. The Fish and Wildlife Commission will generally consider proposals to adjust harvest season structure and/or harvest quotas every two years during the biennial season setting process.

Step 2 – Set objectives

Objectives must be clear and measurable. These objectives are benchmarks against which to compare the potential effects of management alternatives. They also serve as

means to evaluate how effective management actions were, once implemented.

There may be discrete objectives for population composition and trend, hunter experience, harvest distribution, rates of reported conflict, etc. It's important that an objective identifies a clear time by which it should be met and clearly describes how progress toward that objective will be measured.

An example of clear and measurable objectives would be:

“The 2023 Northwest ecoregion estimated population of independent age mountain lions will be between 1,100 and 1,300 animals”, and

“The proportion of >5-year-old male mountain lions harvested in the Northwest ecoregion will exceed 12% during 4 of the next 6 hunting seasons”

Step 3 – Develop management alternatives

Identify a set of potential management actions that, based on the best information available, are likely to help meet the objectives.

For example, competing harvest alternatives could be:

Alternative 1: “Offer a total of 160 Special Licenses with a male subquota of 70 in LMUs 100 – 130; maintain a total “any legal” mountain lion quota of 30 in LMUs 132 – 170; and maintain a quota of 30 females and 50 males distributed across LMUs 200 – 203, the MSMA, and 283/285 during the 2018 – 2019 hunting seasons in order to harvest an average of 130 male and 90 female lions annually”, or

Alternative 2: “Offer a total of 200 Special Licenses with a male subquota of 80 in LMUs 100 – 130 and maintain a total any legal mountain lion quota of 30 in LMUs 132 – 170; and maintain a quota of 45 females and 70 males distributed across LMUs 200 – 203, the MSMA, and 283/285 during the 2018 – 2019 hunting seasons in order to harvest an average of 150 male and 110 female lions annually”

Step 4 – Use models to predict the alternatives' effects

Models can describe our current understanding about how a system works and explicitly represent our uncertainties. Models are used to predict likely responses of a resource to management actions.

In our example, biologists would use the Integrated Population Model to evaluate which of the previous alternatives is most likely to move the overall Northwest Ecoregion's independent aged mountain lion population toward the 1,100-1,300-objective range in 6 years and recruit sufficient older age-class toms each year to also meet the harvest-age composition objective. If neither alternative is likely to meet both objectives, new alternatives will be developed and evaluated.

Step 5 – Develop monitoring plans

Design a monitoring plan that effectively tracks the resource's status relative to the objectives. Monitoring must produce data relevant to the management situation that motivated the monitoring in the first place.

For our example, there would be three monitoring plans in place:

- 1. Teeth will be extracted from all harvested lions upon mandatory inspection resulting in a >90% age assignment rate using cementum annuli analysis, and*
- 2. Actual 2018 and 2019 Northwest ecoregion harvest, by sex, will be input into the Integrated Population Model following the 2019 season to reassess population trend relative to the population objective, and*
- 3. A Spatial Capture-Recapture field estimate of lion abundance will be developed for the Northwest ecoregion Trend Monitoring Area in 2023 and Supplemental Monitoring Area in 2024. Biologists will directly compare the 2018 and 2023 Trend Monitoring Area population estimates. The relationship between observed mountain lion abundance and the RSF for both monitoring areas will be combined to produce an estimate of independent age mountain lions in 2024, which will be input into the IPM.*

Step 6 – Make management decisions

Select management actions that are likely to move the resource toward the objectives.

For our example:

Managers will recommend a preferred alternative or alternatives to the Fish and Wildlife Commission who will make a management decision for the upcoming hunting seasons.

Step 7 – Monitor the resource

Measure the resources' response to management actions.

FWP will implement the monitoring plans described in Step 5.

Step 8 – Assess management success

Compare the predicted vs. observed changes in the resource's status to improve our understanding of the system and allow better decisions to be made in the future.

For our example:

Monitoring data indicate that the overall population objective has been (or is likely to be) achieved but the harvest-age composition objective has not.

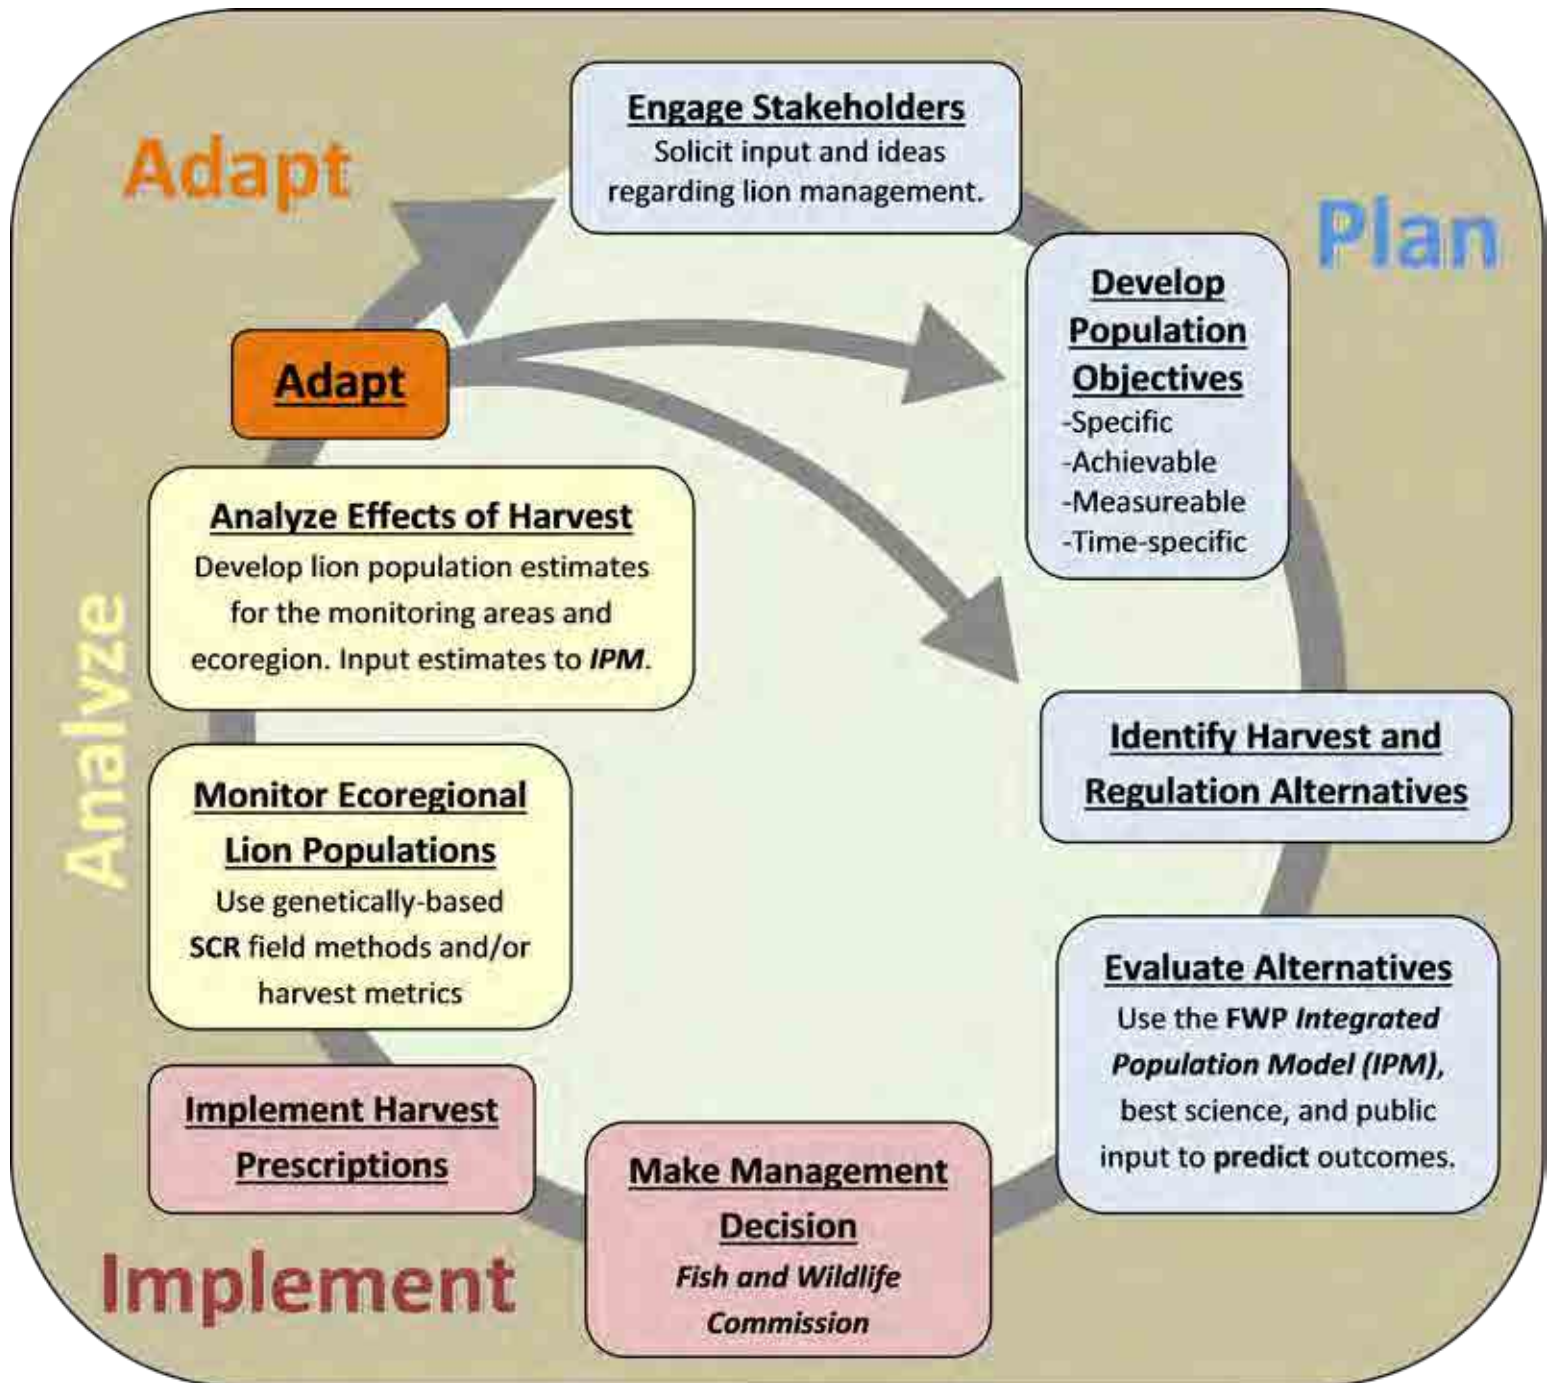

Step 9 – Repeat the process

Cycle back to Step 6 and, less frequently, to Step 1. Predictive models will improve based on new information. Objectives can change over time.

For our example:

Managers propose a revised harvest prescription that maintains female harvest at a similar level while reducing male harvest.

Figure 23. Adaptive mountain lion harvest management process.

CHAPTER 9

REGIONAL MANAGEMENT CONSIDERATIONS AND OBJECTIVES

Mountain lion populations will be monitored, modeled, and managed at the ecoregion scale. However, it is important to recognize the social and biological issues that are unique to each FWP administrative Region. FWP wildlife managers are experts in their regional landscapes and communities, opportunities to gather public input are organized regionally, and regional managers develop and submit individual hunting season proposals for Fish and Wildlife Commission consideration. Responses to human-lion conflicts are also coordinated by Regional managers and field staff.

This Strategy will require that FWP and the public work across FWP regional boundaries to develop management objectives and alternatives for each of the 4 broader

mountain lion ecoregions. They will also need to collaboratively work to distribute an ecoregion's harvest prescription because the ecoregion's constituent LMUs lie within more than one FWP administrative region.

This chapter presents each FWP administrative region's mountain lion management history and some local factors that will need to be considered as ecoregional management proposals are developed and evaluated.

This Strategy will require that FWP and the public work across FWP regional boundaries to develop management objectives and alternatives for each of the 4 broader mountain lion ecoregions

REGION 1

Approximately 80% of FWP Region 1's area is high-quality mountain lion habitat (Chapter 3), the most of any of the state's 7 administrative Regions (Figure 24). Because of this, and the Region's abundant white-tailed deer, it may support the highest overall mountain lion density in the state. Mountain lion habitat occurs almost entirely on either public or publicly accessible private land and tracking snow is generally present throughout the Winter Season.

Region 1 lion harvest was unlimited until specific LMU quotas were adopted in 1986. Harvest was managed using a system of total quotas and female subquotas through 1994, followed by a total quota system until 1999 (Table 8).

Regional harvest steadily increased throughout the 1990s (Table 7) and the average age of harvested lions also increased during this same period. In the late 1980s, only 38% of the harvest was made up of older (≥ 3 years) lions. That proportion increased to 66% older individuals as the harvest steadily increased from 1990 to 1996.

Mountain lion harvest increased during the 1990's such that even historically-high quotas were exceeded in 1995 and 1997. Harvest then began to decline in 1999 following a drop in harvest-age structure that began in 1997. The effect of high harvest levels (especially of females) was likely exacerbated by a severe winter in 1996-1997 that significantly reduced both the Region's deer populations and subsequent recruitment (Montana Fish, Wildlife and Parks 2006).

Quota-based, General License harvest regulations did not limit nonresident hunter participation during the 1990s and conflicts between nonresident/outfitted hunters (who in some years took nearly half of all Region 1 lions) and resident hunters became unacceptably common.

Between 1997 and 2004, only 39% of harvested lions were 3 years old or older. In 2000, declines in the Region's age-in-harvest and overall harvest, combined with a public demand to prioritize resident hunter opportunity, led the Fish and Wildlife Commission to change the Region's management approach. The Commission restricted

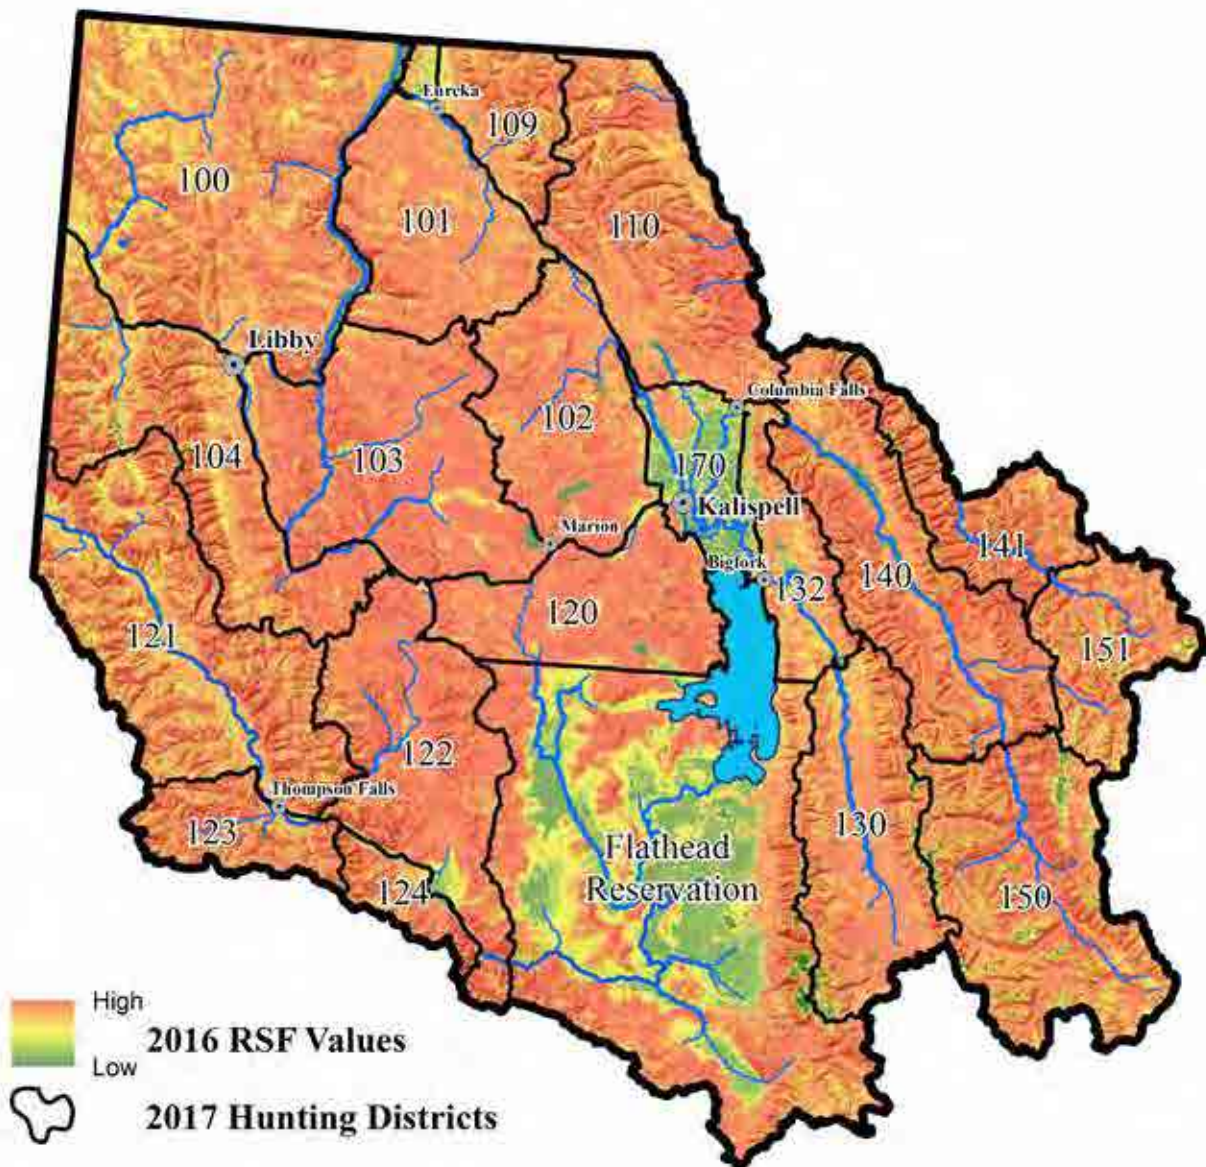

Table 7. Region 1 mountain lion harvest, 1971 – 2016.

resident and nonresident harvest by requiring a Special Lion License, obtained through a drawing, across much of the Region that year.

In 2005, a combination of limited entry (Special Licenses) and quota systems were adopted in Region 1. The goals of this harvest strategy were to 1) maintain a high-quality hunting experience, 2) limit nonresident hunter harvest in some LMUs, 3) prevent the overharvest of adult females while recruiting more mature males into the population, and 4) prevent FWP regulations from limiting effective harvest in LMUs where tolerance for lion presence was low. Region 1 documented a higher percentage (55%) of older individuals (≥ 3 years) in the harvest during the years following the change (2005 – 2013). In 2014, the Commission adopted a male subquota, limited entry hunting season type for most Region 1 LMUs.

Figure 24. FWP Region 1 2016 mountain lion winter RSF and hunting districts.

In 2017, 13 of the Region’s 18 LMUs issued a limited number of Special Licenses, available through a drawing, with nonresidents limited to 10% of the total number of Licenses offered. The Region’s remaining 5 LMUs managed harvest using General Lion Licenses; harvest in these Units is generally limited by overall quotas and male subquotas. LMU 170 (the Flathead Valley) is the single exception. An unlimited number of lions could be taken each season in this highly developed, urban, LMU. In practice, however, lions are rarely harvested in LMU 170—only 4 lions were taken by hunters in that Unit between 2007 and 2016.

The predominant use of limited Special Licenses in Region 1 has effectively emphasized resident hunter harvest—

between 2007 and 2016 an average of only 13% of harvested lions were taken by nonresidents there.

Region 1 lies entirely within the Northwest mountain lion ecoregion (Figure 25). The Region’s biologists and public will work with their counterparts in Region 2 (that includes the remainder of the Northwest ecoregion) to adaptively manage the ecoregion’s mountain lion population.

Model Harvest Regulation Season Type 1: Special Mountain Lion License and **Season Type 2: General License** will initially need to be employed to address Region 1’s diverse social and biological management needs.

Figure 25. FWP Region 1 hunting districts and mountain lion ecoregion.

Specific harvest and population objectives will be identified and evaluated through the adaptive harvest management process (Chapter 8). However, Region 1 will generally advocate for limited adult female harvest in the Northwest ecoregion so that the overall, long term, population growth rate within the ecoregion is stable or positive. Region 1 will also support harvest proposals designed to recruit and maintain older age-class males in the ecoregion. Mountain lion harvest across the Region will be generally distributed in proportion to the various LMUs' estimated mountain lion habitat quantity and quality.

Region 1 will recommend season types that effectively limit nonresident hunter harvest, where necessary, to maintain

a high-quality hunting experience for resident mountain lion hunters.

Region 1 will also ensure that hunting regulations do not limit hunter harvest in densely populated areas of the Region (such as LMU 170) where human-lion conflicts are likely. Human-lion conflicts will be mitigated using both hunter harvest and effective responses to individual incidents that are consistent with the Depredation and Control Guidelines (Appendix 3).

REGION 2

High-quality mountain lion habitat is distributed throughout FWP Region 2, especially in the lower Clark Fork, Blackfoot, and portions of the Bitterroot Valleys (Figure 26). The Region has a diverse and abundant ungulate prey base. Recent field estimates of mountain lion abundance (using SCR) in portions of the Blackfoot and Bitterroot Valleys were high compared to the range of densities previously reported for western North America.

Important field research into mountain lion ecology, the effects of harvest, and new population monitoring techniques has been conducted in Region 2 and the results of this work were used to develop this Strategy (Hornocker & Negri 2009, Robinson & DeSimone 2011, Russell et al. 2012, Proffitt et al. 2015).

Region 2 lion abundance and harvest opportunity increased dramatically during the 1990s, reaching a peak of 267 lions taken (more than half of them females) during the 1998 seasons (Table 9). Historically high harvest continued through the late 1990s even after the severe winter of 1996-97 reduced deer and elk herds in several areas of the Region.

By the early 2000s, the average age of harvested lions had fallen. FWP significantly reduced harvest quotas during the 2000s after both ongoing research and hound handlers' field observations indicated that lion numbers had declined (Table 10). Research in the Garnet Mountains (Robinson & DeSimone 2011), public observations, and rates of human-lion conflict all suggested that Region 2 lion populations had recovered to near 1990s levels by the late 2000s.

In 1994, Region 2 established a new LMU—the Missoula Special Management Area—surrounding the densely populated Missoula Valley. FWP prescribed high quotas (that were rarely met) in this LMU to ensure that hunting regulations were not publicly perceived as limiting legal hunter harvest in this high conflict area.

Tension between Region 2 nonresident/outfitted and resident hunters increased during the 1990s and early 2000s; By 2005, nonresident hunters harvested nearly

50% of the Region's lions. These conflicts were particularly acute in the Bitterroot and Blackfoot watersheds. In 2006, Region 2 began to require that nonresident hunters draw a limited Special Lion License to harvest a lion in most Region 2 LMUs—the number of these nonresident Special Licenses were equal to 10% of the total harvest quota.

In 2008, the Commission began to require that both resident and nonresident hunters draw a Special Lion License to harvest a lion in most of the Region's LMUs. This season type resulted in unpredictable harvest rates and female harvest objectives were rarely met using Special Lion Licenses alone. Therefore, in 2012 the Commission adopted a Late Winter Season (beginning 2/1) in most Region 2 LMUs. During the late Winter Season, hunters with a General Lion License could harvest lions until any quotas previously unfilled by Special Lion License holders

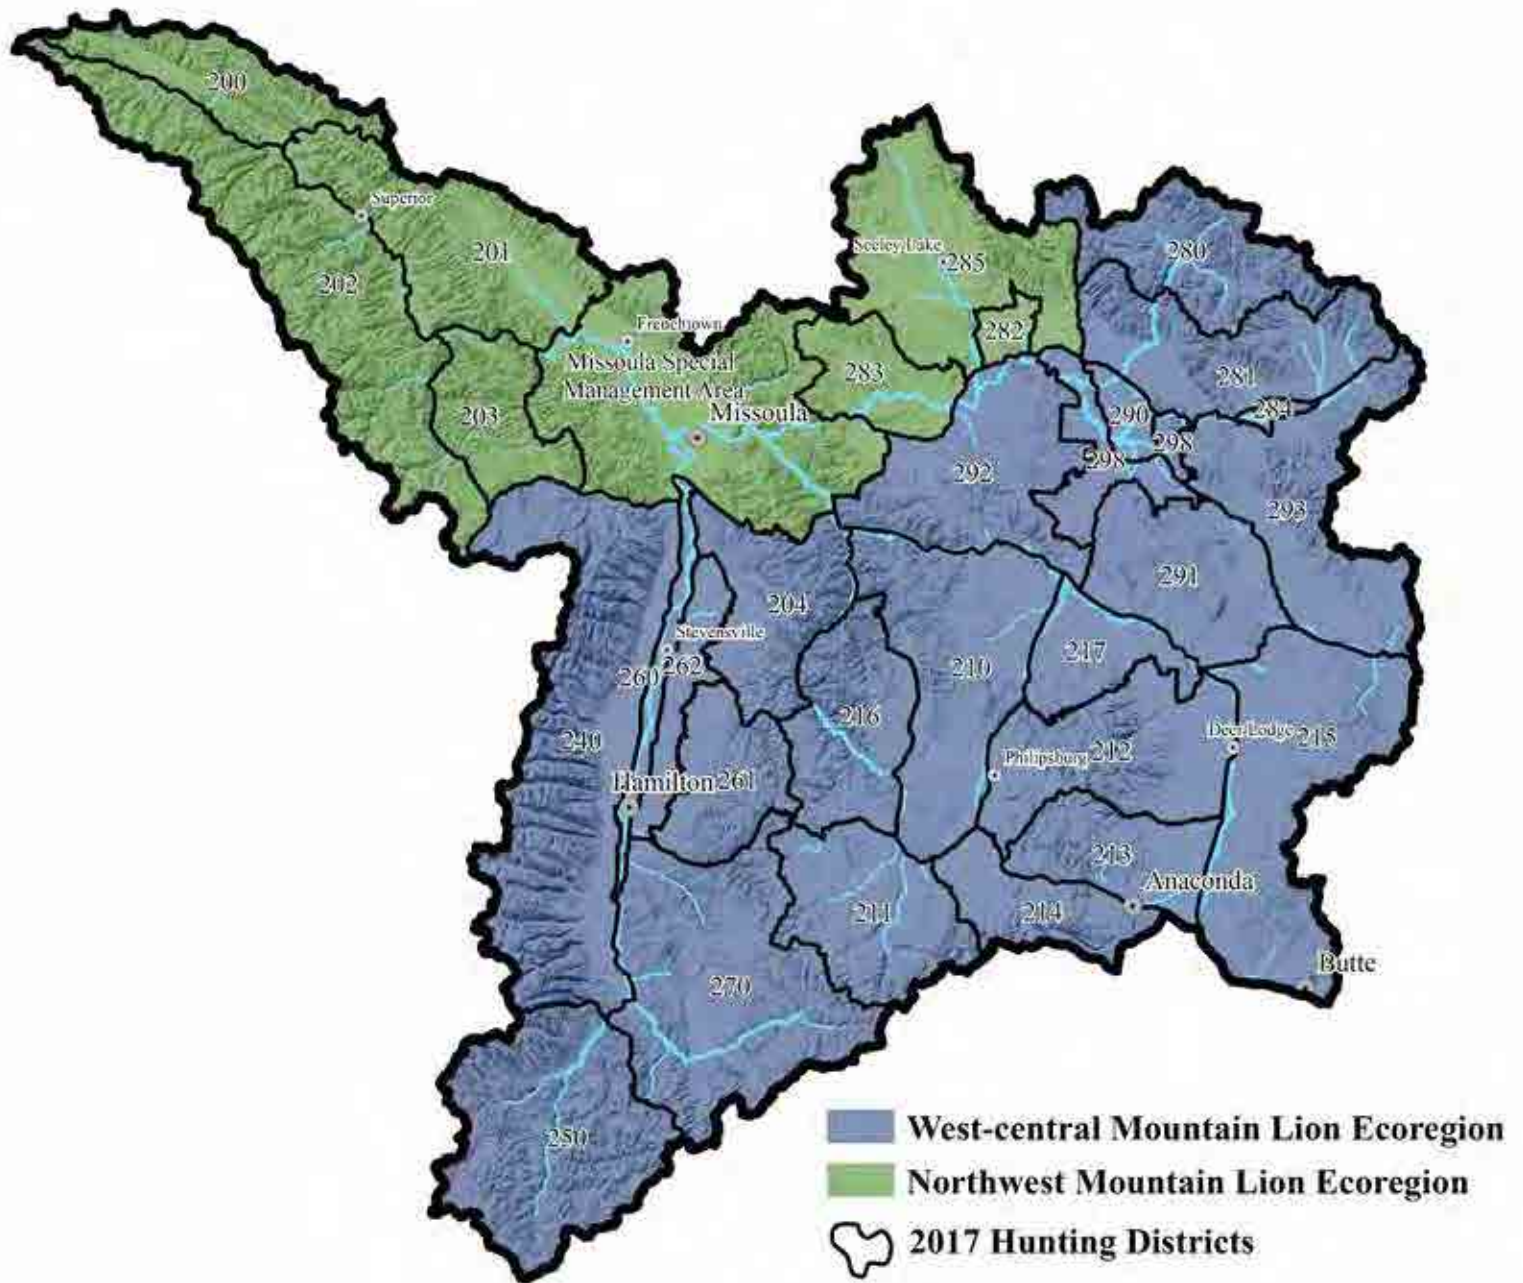

Figure 26. FWP Region 2 2016 mountain lion winter RSF and hunting districts.

were met (this became known as a “hybrid” season). Although this season type allowed more precise harvest management, nonresident participation was unlimited during the Late Winter Season and Region 2 nonresident harvest rates more than doubled after the Late Winter Season was adopted.

Most Region 2 lion habitat is on public or publicly accessible private land. Tracking snow is generally present during the Winter Season, although snow conditions are more likely to limit effective harvest in the upper Clark Fork and Bitterroot drainages.

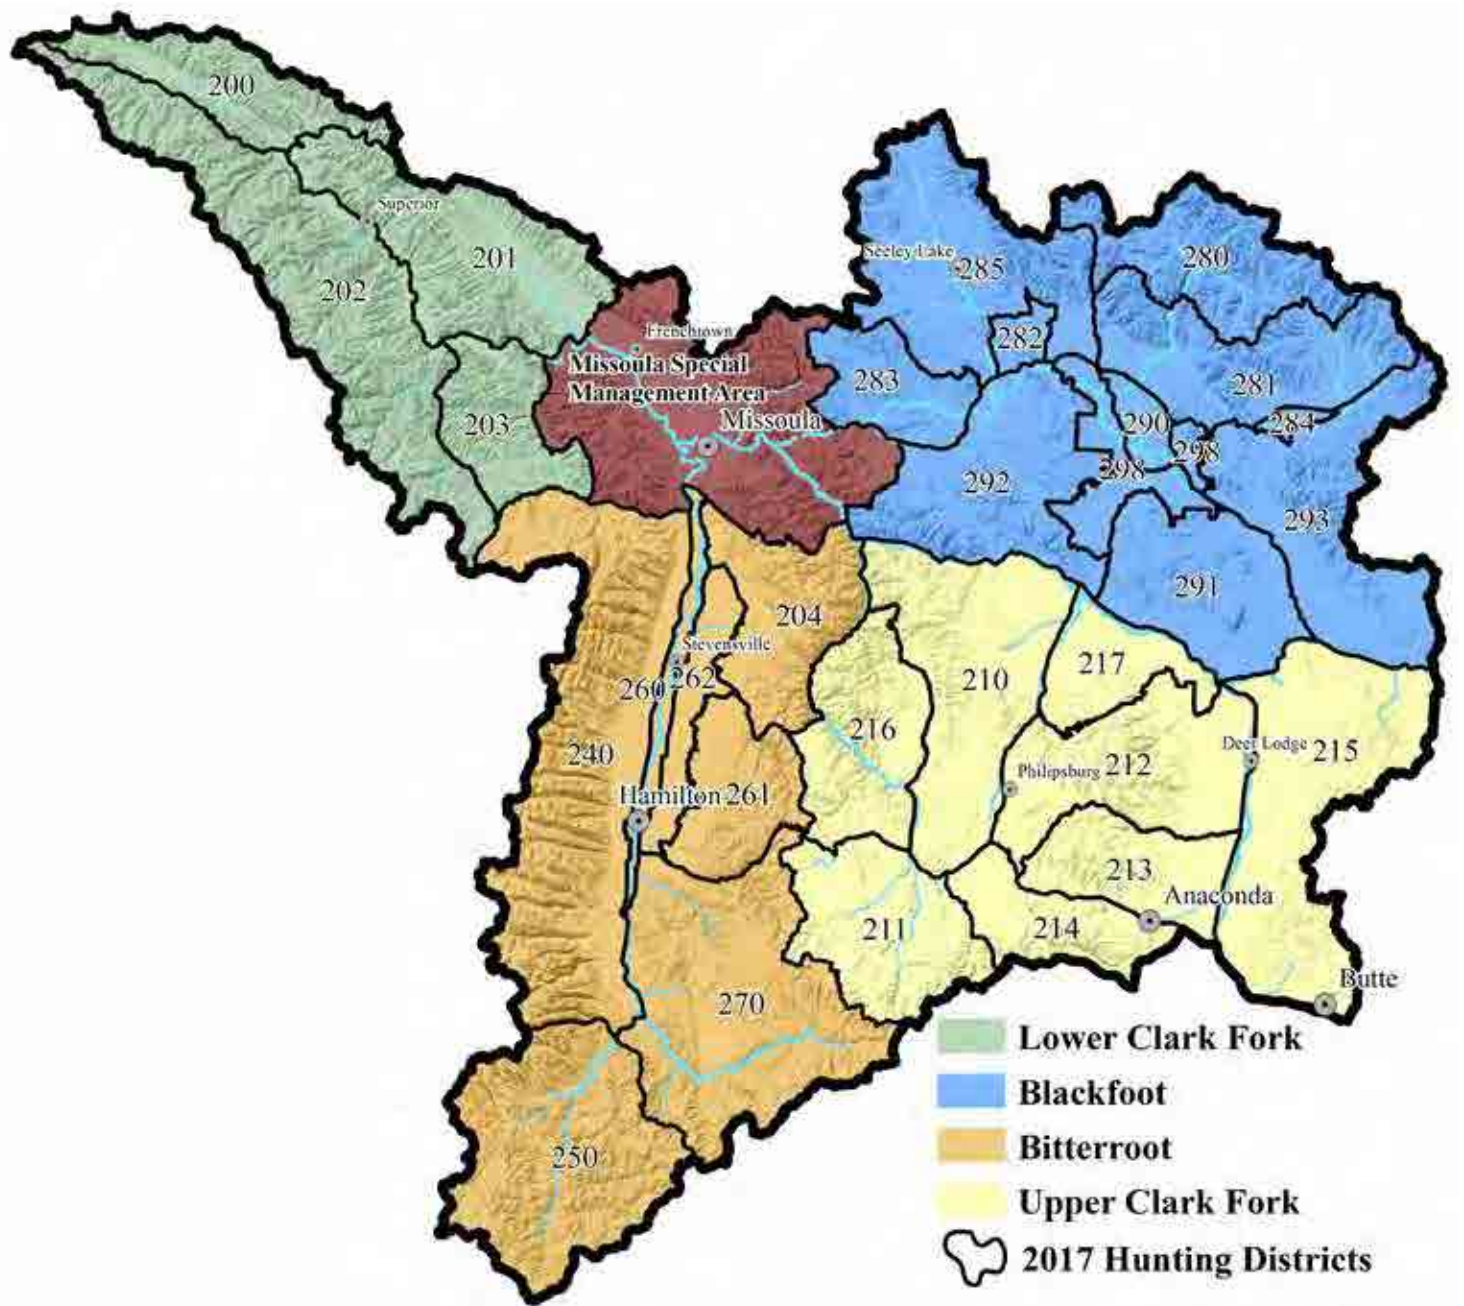

Figure 27. FWP Region 2 hunting districts and mountain lion ecoregions.

FWP Region 2 includes portions of both the Northwest and West-central mountain lion ecoregions (Figure 27). Region 2's biologists and public will work with their counterparts in Regions 1, 3 and 4 to set specific objectives for, and adaptively manage, these ecoregions' mountain lion populations.

Region 2 is comprised of 5 distinct management areas: the Region's four major watersheds and the Missoula Special Management Area (Figure 28). Region 2 will initially recommend either Model Harvest Regulation **Season Type 2: General License** or **Season Type 3: Resident General License, Nonresident Special Mountain Lion License** for each of these distinct areas.

Figure 28. Region 2's four major watersheds and the Missoula Special Management Area.

Specific harvest and population objectives will be identified and evaluated through the adaptive harvest management process (Chapter 8). In general, Region 2 will support ecoregion management objectives that result in generally stable lion populations and annual harvest levels. FWP will consider adjustments to management prescriptions based on contemporary monitoring data and significantly changed local circumstances.

Region 2 will minimize human-lion conflicts using both hunter harvest and effective responses to individual

incidents that are consistent with the Depredation and Control Guidelines. Hunting regulations and harvest quotas for the Missoula Special Management Area will not significantly limit hunter harvest opportunity there during open seasons.

Region 2 will recommend season types that effectively limit nonresident hunter harvest where necessary to maintain a high-quality hunting experience for resident mountain lion hunters.

REGION 3

Mountain lions occur throughout their suitable habitat in southwest Montana's Region 3 (Figure 329). The Region has a diverse and abundant ungulate prey base that inhabits a mix of publicly accessible and privately-owned land.

Lion abundance increased in Region 3 during the 1980s and 1990s but, unlike other areas of the state, did not appear to fall as sharply during the 2000s. Instead, anecdotal evidence and harvest records suggest that mountain lion distribution and abundance have remained relatively stable

Figure 29. FWP Region 3 2016 mountain lion winter RSF and hunting districts.

in the Region since the mid-1990s. Variation in the total annual harvest (Table 11) is almost entirely due to changes in female harvest quotas. Sustained harvest in the late 2010s was similar to harvest levels in both Regions' 1 and 2 during the same period.

Region 3 generally managed harvest using simple harvest quotas and female subquotas (Table 12). However, the Region historically designated a large number of LMUS (23 in 2017)—the number of these individual LMUs may be reduced during future season setting processes. Region 3 quotas serve as harvest limits in all LMUs.

Public access to winter mountain lion habitat is mixed, although most harvest occurs on public land. Winter snow tracking conditions vary annually and can, at times, limit effective harvest. Nonresidents accounted for 15% of all successful hunters in the Region between 2007 and 2016 even though there was no regulatory limit on nonresident hunter harvest during that period.

Region 3 manages LMU 309, (the Gallatin Valley around Bozeman) as a Special Management Area. Lions are rarely harvested in this LMU (2 between 2007 and 2016), but the quota is high enough to ensure that FWP regulations do not limit legal harvest. Similarly, the Fall Season Without Dogs in LMU 309 opened with the beginning of the Deer/Elk Archery Only Season and remained open through the General Deer/Elk Season. The Region also designated a specific quota for the Spanish Peaks portion of LMU 311 to reduce lion predation on the resident bighorn sheep herd.

FWP Region 3 contains portions of both the Southwest and West-central Mountain Lion Ecoregions (Figure 30). Region 3's biologists and public will work with their counterparts in Regions 2, 4 and 5 to set objectives for, and adaptively manage, these ecoregions' mountain lion populations.

Region 3 will be able to meet lion management objectives by primarily using Model Harvest Regulation **Season Type 2: General License**.

FWP and public stakeholders will determine and evaluate specific lion population objectives using the

Adaptive Harvest Management process (Chapter 8). The Region will generally support objectives for stable lion populations and annual harvest, while considering contemporary monitoring data and local circumstances. Region 3 will recommend the least complex harvest regulations that will allow management objectives to be met.

Hunting regulations will not limit hunter harvest in highly developed areas where human-lion conflicts are likely (such as LMU 309) or where suppression of local lion density is desired (such as the Spanish Peaks portion of LMU 311).

FWP will minimize human-lion conflicts using both hunter harvest and effective responses to individual incidents that are consistent with the Depredation and Control Guidelines.

REGION 4

Mountain lion abundance and distribution generally increased in Region 4 from the 1980s to mid-2010s — only toward the end of that period was all suitable habitat (including the Missouri River Breaks and Sweet Grass Hills) fully reoccupied (Figure 31).

Region 4 includes portions of both the West-central and Eastern Mountain Lion Ecoregions (Figure 32). Most of the Region’s high-quality lion habitat lies within the West-central ecoregion, although quality habitat exists in portions of the Eastern ecoregion along the northern Rocky Mountain front, the Highwoods, the Sweet Grass Hills and Missouri River Breaks. Most lion harvest within Region 4 occurs on public land.

Region 4’s annual harvest peaked in the late 1990s and stabilized somewhat below those historic high levels in the mid-2010s (Table 13). The Region traditionally managed harvest by prescribing male and female quotas to individual LMUs. Nonresident hunters accounted for 19% of all lions harvested between 2007 and 2016; less than 20% of those successful nonresident hunters used the services of an outfitter.

Reducing and mitigating conflicts between lions and agricultural interests is a high Regional priority. Region 4 staff will actively respond to potential and ongoing mountain lion conflicts, consistent with the Depredation and Control Guidelines, in order to maintain landowner tolerance for lions.

Region 4 will generally support management objectives that maintain stable lion abundance, distribution, and harvest across the Region’s suitable habitat. Region 4’s biologists and public will work with their counterparts in other Regions to set objectives for, and adaptively manage, the West-central and Eastern ecoregions’ mountain lion populations.

Region 4 will recommend the least complex harvest regulation that will allow management objectives to be met, primarily using Model Harvest Regulation **Season Type 2: General License** with male and female quotas.

REGION 5

Mountain lion hunter harvest opportunity was generally stable in Region 5 from the 1990s to late 2010s. However, annual harvest success varied year-to-year depending on winter snow-tracking conditions. Most of the Region's publicly accessible, high-quality, lion habitat lies in its peripheral mountain foothills (Figure 33). While the Region includes portions of both the Southwest and Eastern Mountain Lion ecoregions, most lions are harvested in the Southwest ecoregion (Figure 34). Nonresidents took 18% of all lions harvested in Region 5 between 2007 and 2016, most without the aid of an outfitter.

Although Region 5 harvest is well distributed across suitable lion habitat, individual LMU quotas may not be

consistently reached because annual harvest is dependent on the presence of adequate tracking snow. Region 5 may consider reducing the number of Regional LMUs to simplify harvest management.

Managers will generally recommend harvest objectives that maintain stable lion abundance, distribution, and harvest across all suitable habitat in Region 5. Biologists and the public will work with their counterparts in other Regions to set objectives for, and adaptively manage, the Southwest and Eastern Ecoregions' mountain lion populations.

Region 5 historically used overall LMU quotas (with female subquotas) to manage harvest (Table 16). The Region will be able to meet lion management objectives by using the similar Model Harvest Regulation **Season Type 2: General**

Figure 33. FWP Region 5 2016 mountain lion winter RSF and hunting districts.

License season type that employs individual male and female quotas.

Minimizing human-lion conflicts and livestock depredation is a high Regional priority. Region 5 will use both hunter harvest and effective responses to individual incidents that are consistent with the Depredation and Control Guidelines to reduce potential conflicts.

REGION 6

Most suitable mountain lion habitat in Region 6 lies in the Bears Paw and Little Rockies ranges, as well as along the Missouri River (Figure 35). A significant portion of the Region's lion habitat is included within the Rocky Boy's and Fort Belknap Reservations—FWP does not have wildlife management authority within these jurisdictions.

There was no open mountain lion hunting season between 1976 and 1992 in Region 6 (Table 18); mountain lions became increasingly common in the Region 6 during this period. Harvest quotas have remained relatively stable since hunting seasons were re-opened in 1993 but the annual FWP managed harvest varies annually depending on winter tracking conditions, hunter access, and individual hunters' participation in the harvest season (Table 17).

Mountain lion harvest that occurs on the Rocky Boy's and Fort Belknap reservations may not be reported to FWP, and thus, regional harvest totals should be viewed as minimums. Kunkel et al. (2012) documented a relatively high annual hunter harvest rate and low adult survival for Region 6 lions during their study. The authors suggested that Region 6 lion populations may be sustained by immigration rather than local recruitment. If so, continuing to protect adult females from harvest may allow local reproduction to supplement lions that disperse into the Region.

Lions are only likely to be resident in hunting districts 680, 690, 621, 622, 631 and 632. The remainder of the Region may be considered a Special Management Area where tolerance for lions is low. In this area, liberal quotas may be recommended so that hunter harvest is available when needed to minimize conflict while still allowing for lion movement between resident populations.

All of Region 6 lies within the Eastern Mountain Lion ecoregion (Figure 36). Routine lion abundance estimates and population modeling will not be available in this ecoregion. Because of annual variations in

tracking snow cover, annual harvest varies independent of population trend. Regional managers will therefore rely on indirect indications of lion abundance and public input to monitor lion populations. Region 6 may also choose to produce a baseline Regional abundance estimate (either alone or in collaboration with Tribal partners) following SCR or other field methods (Chapter 5) if funding is available.

Region 6 will be able to meet lion management objectives by using Model Harvest Regulation **Season Type 2: General License** with individual male and female quotas or subquotas.

REGION 7

Mountain lions have expanded their range into eastern Montana since the 1980s and are now found in all suitable Region 7 habitats (Figure 37). The first mountain lion hunting season in Region 7 occurred in 1985 but no harvest was recorded until 1990. FWP incrementally raised quotas as the Region's lion abundance and distribution increased. Mountain lion age-in-harvest, harvest sex ratios, and hunter effort remained stable through the late 2010s.

Because lions only recently recovered in Region 7, neither biological nor social carrying capacities are as well known. Incidents of human-lion conflict and livestock depredation remained low through the mid-2010s and landowners were generally tolerant of mountain lion presence.

Region 7 lies entirely within the Eastern mountain lion ecoregion (Figure 38). Estimates of lion abundance will not be routinely produced using SCR or other field methods for this ecoregion. Managers will need to instead rely in indirect indices of abundance, harvest success, and public input to help guide management decisions.

Intermittent winter snow cover in the Region limits hound hunting's effectiveness. Annual lion harvest is correlated with the number of days the Region has snow cover (FWP data). Therefore, Region 7 quotas are more likely to serve as limits on harvest during years when snow conditions are favorable than as reliable annual harvest prescriptions. If quotas are met despite annually variable environmental conditions, managers may consider whether an increase is appropriate. Overharvest in Region 7 is unlikely because these favorable tracking conditions are rare and hunters have limited access to occupied habitat.

Region 7 traditionally prescribed a single, Region-wide, harvest quota. This approach was intended to both maximize hunter opportunity and regulation simplicity. It also allowed flexibility to direct harvest to areas with higher lion densities, more conflicts, or better tracking conditions. Region 7 may continue to comprise a single LMU within the Eastern ecoregion to maintain this management approach.

FWP biologists will carefully monitor harvest distribution within the Region. Region 7 contains three lion management areas: 1) the Ashland Ranger District of the Custer National Forest (where the majority of Region 7 mountain lion harvests occurs) and adjacent lands, 2) the Sioux Ranger District (Chalk Butte, Ekalaka Hills and Long Pines units) of the Custer National Forest, plus several adjacent large tracts of BLM and private land and, 3) lands on and adjacent to the Charles M. Russell Wildlife Refuge.

Patterns in harvest among these units will be tracked over time. If there is a significant reduction in the distribution of harvest that cannot be attributed to tracking conditions

Figure 37. FWP Region 7 2016 mountain lion winter RSF and hunting districts.

or changes in hunter access, the Region may consider management alternatives. Regional managers will also consider the pattern and rate of Regional human-lion conflicts and landowner input when evaluating these alternatives.

Nonresident hunters take an average of 15% of the lions harvested in Region 7 each year.

Minimizing human-lion conflicts and livestock depredation is a high priority in Region 7. The Region will use both

Figure 38. FWP Region 7 hunting districts and mountain lion ecoregion.

hunter harvest and effective responses to individual incidents that are consistent with the Depredation and Control Guidelines to minimize potential conflicts.

Region 7 will be able to meet lion management objectives by using Model Harvest Regulation **Season Type 2: General License**.

APPENDIX 1

POPULATION MONITORING, FIELD PROTOCOL,
AND DATA ANALYSIS

Trend Monitoring Area Selection

FWP identified permanent trend monitoring areas within the Northwest, West-central, and Southwest ecoregions based on the following criteria:

- The area is approximately 2,600 km² (1,000 mi²) in size, and
- The habitat quality (assessed both qualitatively and as predicted by the 2016 RSF) within the trend area is representative of the lion habitat type and quality present in the remainder of the ecoregion, and
- There is current and long term physical and legal access to the majority of the trend monitoring area during winter, and
- Regional wildlife managers and the public are committed to prescribing annual mountain lion harvest rates for the trend monitoring area’s LMUs that are representative of the annual harvest rate in the larger ecoregion.

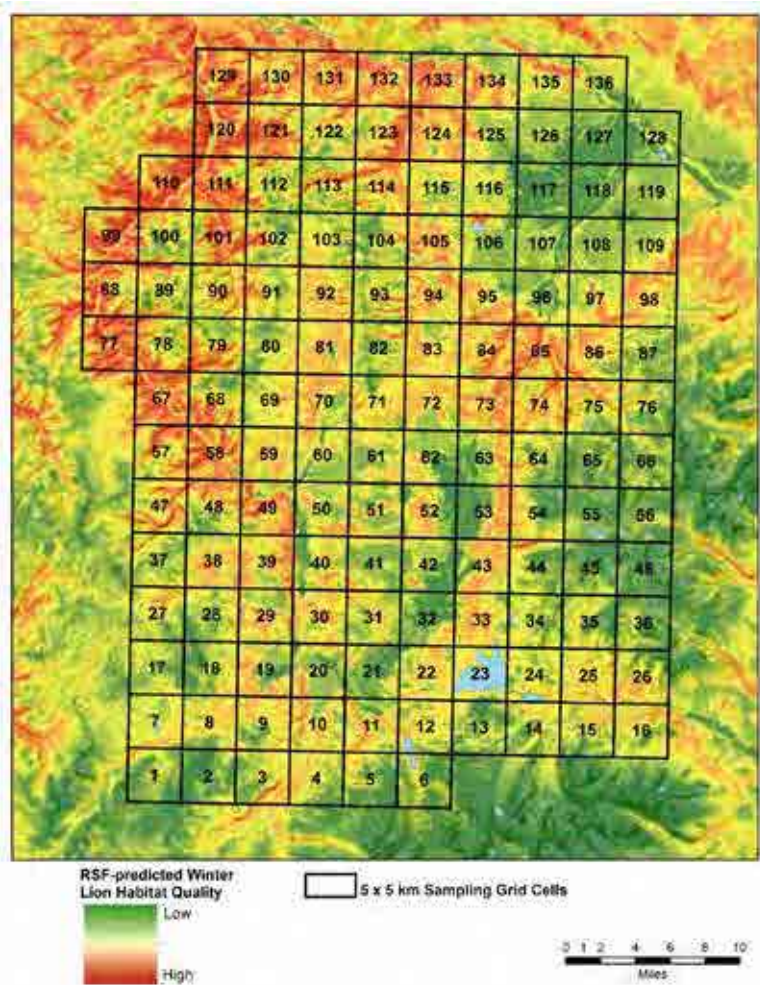

Locations of the Northwest, West-central, and Southwest trend monitoring areas are shown in Chapter 4.

Supplemental Monitoring Area Selection

Supplemental monitoring areas in each of the Northwest, West-central, and Southwest ecoregions may be sampled the year after each ecoregion’s trend monitoring area is sampled. The supplemental monitoring areas will be selected using the following criteria:

- The area is approximately 2,600 km² (1,000 mi.2) in size, and
- There is sufficient physical and legal access (i.e. public land or prior permission from private landowners) to allow sampling of most of the predicted mountain lion habitat in the monitoring area during winter, and
- Harvest rates for the proposed supplemental monitoring area’s LMUs have been representative of the annual harvest rate in the larger ecoregion for at least the last 6 years.

Figure 39. An example of a sampling grid overlaid on a 3,400 km² monitoring area and the underlying 2016 RSF for the area (Proffitt et al. 2014; Upper Clark Fork River, MT).

Initial Field Protocol

Collection and analysis of field data will initially follow methods described in detail by Proffitt et al. (2015). Population monitoring and field sampling techniques may change as improved methods are developed and validated in the future.

Monitoring areas will be sampled between 12/1 and 4/15. Field staff will overlay a 5x5 km grid across the study area and assign each cell a number. Cells will then be stratified into classes according to their habitat quality (RSF value) and a random search order will be assigned to cells in each class. Although each day’s search effort will begin in a randomly assigned grid cell, more overall search effort will be dedicated to cells with higher quality habitat (Figure 39).

Trackers and hound handlers will search their assigned cell(s) to collect genetic samples from mountain lion hair,

scat, and muscle. The location where each sample is collected will be recorded, as will the search route trackers used to survey the cells (Figure 40).

When a fresh track of a suspected independent-aged mountain lion is located, the hound handlers will attempt to tree the lion and collect a muscle sample using a biopsy dart fired from a pneumatic gun. The tracks will then be backtracked and inspected to determine if the lion was independent or associated with a family group—if it was traveling with other animals, the group size will be recorded. Sex of the treed lion will be determined based on genetic analysis.

When older mountain lion tracks are located, a tracker or hound handler will backtrack and collect any hair or scat samples present along the track. All field crews will use a Global Positioning System to record the length and location of their search effort (Figure 40).

Figure 40. An example of the distribution of search effort within a SCR sampling area. In total, 12,785 km of trails within 127 grid cells were sampled over 121 days (Proffitt et al. 2014; Upper Clark Fork River, MT).

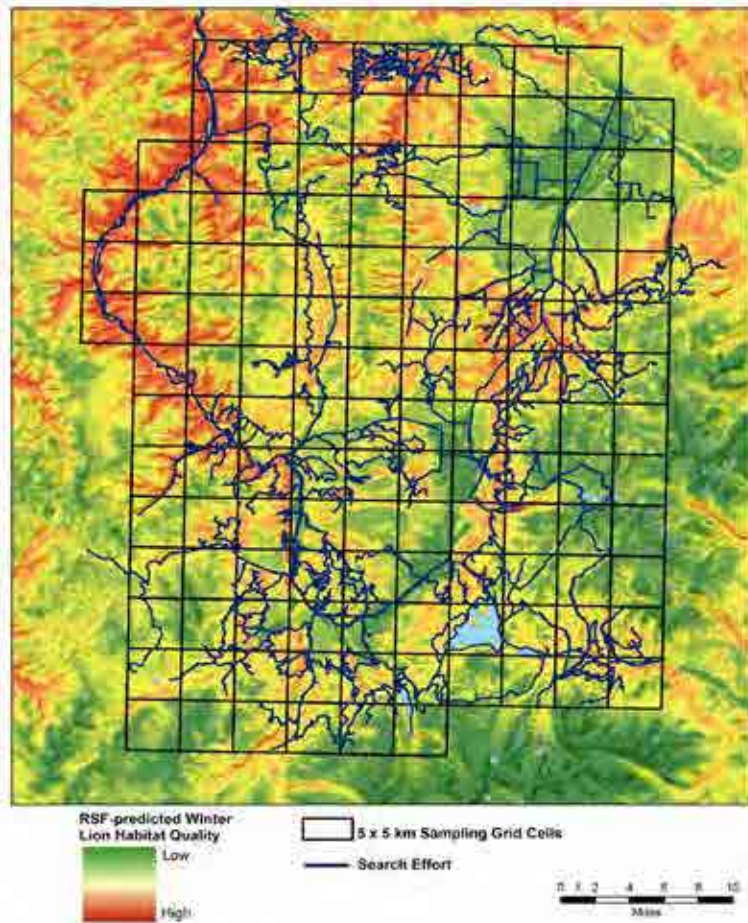

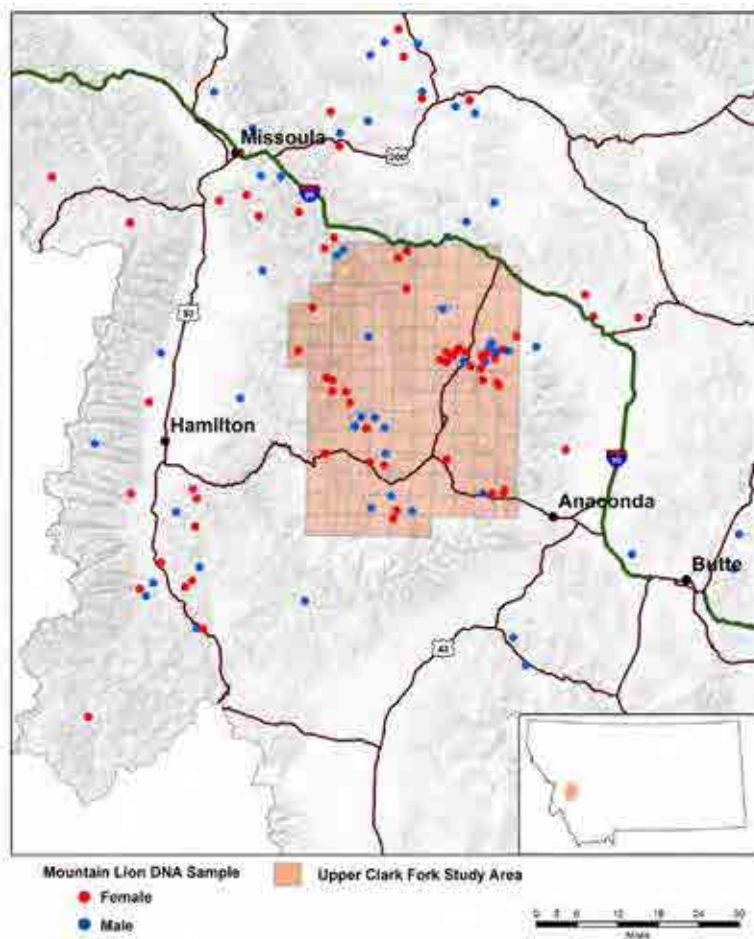

Figure 41. An example of a SCR sampling area and the locations of 132 mountain lion tissue samples (from both field sampling and harvest) that had DNA successfully extracted and analyzed to determine individual ID (Proffitt et al. 2014).

In Montana, the hide and skull of all harvested mountain lions must be presented to a FWP employee within 10 days. FWP will collect genetic samples from all known lion mortalities that occur in or adjacent to the monitoring area. Hair and muscle samples from these lions will be genetically analyzed to determine sex and the individual lions' identities (Figure 41).

Field Sampling Recommendations

A "sample" is a successfully extracted and identified individual mountain lion DNA sequence. Because not all non-invasive DNA samples will generate amplifiable DNA, not all material collected in the field will provide a useful DNA sample. Even after a single sample is collected in a cell, field staff are generally encouraged to continue to expend effort in that cell to obtain either additional lower quality samples (scat, hairs) or a high-quality sample (muscle biopsy). For hound handlers, this means collecting

a biopsy dart sample, and a backup high-quality hair sample. For snow backtrackers, multiple scat samples from different scats, and/or hair samples are ideal.

Field staff will collect tissue from biopsy darts, scats from backtracking, hairs from both biopsy darting (as a backup sample) and hairs from snow tracking, and harvested lion muscle samples. During previous studies (Russell et al. 2012, Proffitt et al. 2015) DNA extraction success was highest for muscle/biopsy samples and lowest for hair and scat. Because not all biopsy samples generate successful DNA sequences, a second set of high-quality hair samples (with follicles attached) should also be collected. Hound handlers should collect these samples opportunistically while tracking the animal to the tree, then search for hair and/or scat around the tree and while back tracking from the tree.

There is a critical difference between when a survey cell has been searched versus when a cell has been successfully sampled. Survey effort was an important predictor of detection in previous SCR studies of lions (Russell et al. 2012). Therefore, field staff must carefully collect a GPS track log of all daily search effort. If a cell is searched and lion sign is present but a sample is not obtained, then the cell was not successfully sampled.

Search effort should be spatially distributed by randomly assigning cells to be searched each day. These random grid cells are the starting point for the day's search. However, if new tracks are encountered while traveling to the day's starting grid cell, the tracker should follow those tracks if that grid cell has not been successfully sampled yet. If tracks of a lion previously captured in that grid cell are detected, however, the tracker should proceed to the day's assigned starting location.

The hound handler/tracker should confine search activity to the assigned focal cell or its 8 adjacent grid cells on any particular day. Field crews may choose to skip a randomly assigned cell if multiple teams are working nearby and the randomly assigned cell could lead to survey overlap. Likewise, assigned cells may be skipped if that cell has been surveyed within the previous month and a high-quality sample already obtained. Field crews may choose

to skip assigned cells if conditions in the assigned cell will not allow snow tracking.

Once a hound handler is assigned a starting grid cell, subsequent sampling effort may proceed in one of several ways. If the assigned cell and adjacent cells are searched, no sign is detected, and the hound handler believes the area is likely void of lions at that time (e.g. too high of an elevation, too much snow, etc.), the hound handler will receive a new randomly assigned starting cell the next day. The cell will remain on the sampling list for that period.

If after the assigned cell and adjacent cells are searched, all tracks are followed, and the hound handler believes that all lions currently detected within the area have been sampled, the cell(s) from which samples were collected will be removed from the sample list for that period. The hound handler will then get a new starting cell from the sampling list the next day.

If the assigned cell and adjacent cells are searched, multiple tracks are found, and the hound handler believes that NOT all lions currently within the area have been sampled, only the cell(s) from which samples were collected will be removed from the list. The hound handler will then return to the area and continue to work there until their shift is over, or they believe they have sampled all of the lions thought to be in the area. A new starting cell from the sampling list will be assigned the next day.

All samples will be carefully stored in desiccant and labeled with a unique sample ID. Hound handlers and trackers will record their daily search effort using GPS tracks from GPS units.

Estimating Ecoregional Lion Abundance

Montana FWP will monitor and manage mountain lions within large (>35,000 km²) ecoregions. To do so, managers will need to periodically estimate lion population size within these ecoregions and make predictions about the effect of future harvest at this scale. Once an overall harvest prescription has been developed for an ecoregion, individual harvest limits will be assigned to the ecoregions' LMUs to distribute harvest and address local management objectives.

Spatially explicit abundance estimates from representative sampling areas can be extrapolated across a broader area of inference to estimate that landscape's population size (Boyce & McDonald 1999). This method of extrapolating animal abundance as a function of RSF-predicted habitat quality has been used to estimate populations of many species (Boyce et al. 2016), including mountain lions in Montana (Robinson et al. 2015).

Several important factors must be considered when using data collected from sampling areas to estimate a species' population size across a larger area (Wiens et al. 2008, Boyce et al. 2016):

- The relationship between the observed number of animals and available habitat (ie. the 2016 RSF) within a sampling area should be similar to that same relationship across the larger landscape, and
- Harvest management within sampling areas should be representative of the broader area of inference (Reynolds et al. 2016). Specifically, it's important that the long-term mountain lion hunter-harvest rate within an ecoregion's monitoring areas is similar to the harvest rate within the larger landscape for which the estimate is being made, and
- Because a species' abundance can vary over time for reasons unrelated to habitat quality (ie. hunting or changes in prey density), representative sampling area(s) must be periodically re-sampled. This helps ensure that up-to-date relationships between abundance and RSF values are used to estimate current populations.

Producing Ecoregion Population Estimates

The relationship between mountain lion density and habitat within an ecoregion's monitoring area(s) will be most similar to other areas within that same ecoregion. Therefore, the mountain lion abundance data collected on monitoring areas will only be used to estimate the population size of the ecoregion where that monitoring area is located—they will not be used to develop population estimates for other ecoregions.

Even within ecoregions, the relationship between mountain lion abundance and habitat quality varies. To improve the

accuracy of an ecoregion's population estimate, FWP may initially collect data from both a fixed Trend Monitoring Area (sampled Year 1) and a Supplemental Monitoring Area (sampled Year 2). The locations of Supplemental Monitoring Areas may vary over time, Trend Monitoring Area locations will not.

Combining the data collected from both the trend and supplemental monitoring areas may generate a more representative ecoregional estimate of the relationship between lion abundance and the RSF as compared to using data from the trend monitoring area alone (Howe et al. 2013). Therefore, the results of the two subsequent samples will be pooled to describe the current relationship between lion abundance and the RSF within an ecoregion. This pooled relationship will be used to estimate the population of independent-aged mountain lions within that ecoregion.

Ecoregion population estimates will also be produced using monitoring data from the fixed trend monitoring area alone. FWP will compare the estimate derived using the pooled areas' data and the estimate using only the trend monitoring area data. If the two methods consistently produce similar estimates, supplemental monitoring areas will not continue to be sampled.

The initial FWP SCR model predicts the abundance of independent-aged mountain lions at a 4 km² resolution (Proffitt et al. 2015). The following regression equation is an example of one way to estimate the effect of RSF on abundance across the ecoregion:

$$\text{Abundance} = \beta_0 + \beta_1 \cdot \text{RSF} + e$$

FWP continues to test and validate extrapolation methods.

FWP will estimate the mean RSF value over the same spatial extent (4 km²) for both the trend and supplemental monitoring areas, and use these mean RSF values in the regression model. The above regression equation represents the effect of the mean 4 km² RSF on predicted spatial abundances within the pooled trend and supplemental monitoring areas. Using this relationship, FWP will predict mountain lion abundance for the entire ecoregion by extrapolating the observed relationship

between RSF values and mountain lion abundance (Boyce & McDonald 1999). FWP will use the 95% confidence interval around β RSF to estimate the 95% upper and lower confidence intervals around the predicted mean abundance for the ecoregion.

FWP will periodically sample mountain lion populations and produce estimates for the Northwest, West-central, and Southwest ecoregions. An estimate of the overall abundance of mountain lions within these ecoregions will then be developed based on the sampling data. These estimates will be input into the IPM (Chapter 6) as additional data. The IPM then considers the field-based abundance estimates along with harvest prescriptions and lion vital rates when generating more complete predictions of past and future ecoregional population trends.

Data Analysis

To estimate the abundance of independent lions in the sampling area, FWP will initially fit the SCR model to a dataset that includes only samples from independent animals or the adult female of a family group. This eliminates multiple samples from within family groups as well as all groups where only a subadult animal was sampled.

The monitoring period will be divided into sampling periods within the winter season (December, January, February, and March-April). An encounter history will be developed for each detected individual during each sampling period and the detection probability for harvested animals will be adjusted to ‘0’ for the sampling periods following their death.

FWP will initially use a Bayesian SCR model to estimate the number of mountain lions present within the sampling area. This method explicitly incorporates the spatial organization of individuals through the estimation of specific capture probabilities (Efford 2004, Efford et al. 2009, Gardner et al. 2010, Royle et al. 2013).

To account for individuals that had a home range only partially within the sampling area, FWP will buffer the study area by 10 km and estimate spatial densities within the larger area. We will then evaluate potential models

that include all possible combinations of the covariates for search effort and sex, RSF-driven densities, and sex-specific activity center distributions (Russell et al. 2012). We will conduct model selection using a combination of Bayesian Information Criteria (BIC), examination of the posterior significance of the parameters in each model, and two goodness of fit statistics (as described in Proffitt et al. 2015). All of these factors will be weighted by our prior knowledge of mountain lion biology.

We will then estimate the independent-aged lion abundance, with confidence intervals, for the trend and supplemental monitoring areas. Because these abundances are spatially explicit functions of the areas’ underlying habitat quality, we will then extrapolate the monitoring areas’ relationship between abundance and the RSF to produce an estimate of lion abundance across the larger ecoregion.

Cost

Field monitoring will occur at a significant periodic cost to Fish, Wildlife and Parks. The Department will need to hire one staff biologist who will work half-time (6 months) to plan and organize logistics, contract field staff, coordinate day-to-day field operations, and prepare data for analysis. Enough hound handlers will be contracted to successfully sample approximately 60% of grid cells within the Monitoring Area during the four sampling periods. The number of contractors may vary depending on each contractor’s seasonal availability. Genetic analysis of the collected samples will also be contracted through an independent laboratory.

Table 21. Approximate costs (2016) to collect and analyze mountain lion monitoring area data.

Contracted Hound Handlers	\$65,000
Genetic Analysis	\$9,500
Fuel and housing	\$6,500
FWP Biologist (1/2 FTE)	\$32,500
Misc. Supplies	\$2,000
Total	\$115,500

APPENDIX 2

MOUNTAIN LION INTEGRATED POPULATION MODEL DEFINITION AND USER INPUTS

The Montana mountain lion integrated population model is generally described in Chapter 6 and in Nowak et al. 2018. Following are more complete descriptions of the several internal models, the data and prior assumptions that the IPM includes, and an explanation of the controls that users can manipulate to improve the IPM's outputs.

Reproduction Model Definition

The equation describing the number of kittens in year y is as follows:

$$N_{kit,f,y} = (N_{sa,f,y} * P_{sa} * LS_{sa} * 0.5 + N_{a,f,y} * P_a * LS_a * 0.5 * 0.5) * Survival_{kit,y-1}$$

Thus, we calculate the number of female kittens f in year y as a function of the number of subadult sa and adult a females f in year y . For the subadult contribution we take the product of the number of subadults, the age specific pregnancy rate P , and litter size LS .

Only a fraction of the resulting kittens will be female and so the final term in the product simply assumes that half of the kittens born are female. The adult contribution to the kitten population is calculated as the product of the number of adults, the age specific pregnancy rate, litter size, and 0.25 ($0.5 * 0.5$). Because we assume the adult inter-birth interval is 24 months, only half of the adult females are available to reproduce in any given year. We therefore multiply the reproductive term by 0.5. Said another way, the first 0.5 represents the assumption that half of the kittens born are females and the second 0.5 reflects our assumption that the birth interval is 24 months, which results in half of the adult female population giving birth each year.

Multi-state Survival Model Definition

The mountain lion IPM in **PopR** is built around a 4-age class and 2-sex population model. The 4 age classes are **kittens** (0-6 months), **juveniles** (6-18 months), **subadults** (18-30 months) and **adults** (30+ months). We assume a 50:50 sex ratio at birth but, starting with the juvenile age class, each sex is modeled separately. The process model describing lion ecology is represented by a series of equations that describe transitions from one age class to the next each year.

$$N_{kit,f,y} = (N_{sa,f,y} * P_{sa} * LS_{sa} * 0.5 + N_{a,f,y} * P_a * LS_a * 0.5 * 0.5) * Survival_{kit,y-1}$$

$$N_{juv,f,y} = N_{kit,f,y-1} * Survival_{juv,f,y-1} - harvest_{juv,f,y-1} + \epsilon_{juv,f,y}$$

$$N_{sa,f,y} = N_{juv,f,y-1} * Survival_{sa,f,y-1} - harvest_{sa,f,y-1} + \epsilon_{sa,f,y}$$

$$N_{ad,f,y} = (N_{sa,f,y-1} + N_{ad,f,y-1}) * Survival_{ad,f,y-1} - harvest_{ad,f,y-1} + \epsilon_{ad,f,y}$$

where,

$N_{age,sex,y}$

is the abundance of age class age, sex sex in year y

$Survival_{age,sex,y}$

is the survival of age class age, sex sex in year y

P_{age}

is the age-specific pregnancy rate

LS_{age}

LS is the age-specific litter size

$\epsilon_{age,sex,y}$

is the age, sex and year-specific residual variation

Kittens born to subadults and adults the previous year are recruited as juveniles on December 1st each year. The number of subadults and adults is indexed to year **y** based on the number of reproductive females in the population on December 1. The model then takes into account the probability these females will survive until they give birth (assumed to be July 1). We also assume that kittens whose mothers die within the first six months after giving birth will not survive.

The model does not make kittens available for harvest because it assumes they become juveniles on December 1 at 6 months old but would not be independent (and legally harvestable) until after the winter hunting season ends. Although some subadults may reproduce, they do so at a lower rate than adults. Subadults transition to adults on December 1st of the following year. Any mountain lion older than 30 months is considered either an adult male or female. As adults, the model assumes that each sex survives (except for harvest) and reproduces at the same respective rate for the remainder of their lives.

The lion IPM primarily uses estimates and variability of documented vital rates (from the research literature)

rather than raw field data itself (Table 22). This model structure provides several advantages. First, it allows lion research data collected using a wide variety of field sampling protocols to fit into the IPM framework—once the parameter and its error distribution is described it can be entered into the IPM. Because we also include a measure of the field estimate's precision, all sources of uncertainty remain in the IPM.

The general form of the observation model in **PopR** is:

$$\hat{\theta} \sim \text{Normal}(\bar{\theta}, \widehat{SE}(\hat{\theta}))$$

where,

θ = field estimate

$\widehat{SE}(\hat{\theta})$ = estimated standard error of

$\bar{\theta}$ = IPM parameter.

The observation model is like a multi-dimension regression model. The model fitting process seeks to minimize the distance between the IPM parameter (ie. Adult Female Survival) and the associated field estimate simultaneously across all IPM parameters.

Population Reconstruction Model Definition

The IPM uses survival estimates along with the annual harvest rate to reconstruct past mountain lion populations. It is based on examples of live recapture/dead recovery models from the literature that consider sex, age and year specific abundance estimates from records of harvested animals (Brownie et al. 1985, Link et al. 2003, Conn et al. 2008, Buderman et al. 2014). Current hunter harvest by sex, age, and location is input to the model after the close of the harvest season each year. By combining the multi-state survival model with observed harvest data, we can intuitively estimate population size by assuming a simple binomial distribution whose expectation is equivalent to:

$$N_{age,sex,y} = \frac{\text{harvest}_{age,sex,y}}{\text{harvestMortality}_{age,sex,y}}$$

where,

$harvest_{age,sex,y}$

is the number of age a, sex s, animals harvested in year y

$N_{age,sex,y}$

is the age, sex and year specific abundance

$harvestMortality_{age,sex,y}$

describes the relationship between abundance and harvest.

In practice, we implement harvest reconstruction as a binomial distribution:

$$harvest_{age,sex,y} \sim \text{Binomial}(harvestMortality_{age,sex,y}, N_{age,sex,y})$$

Because the model requires that annual harvest data are input annually by both sex and age, FWP determines the age of harvested lions using cementum age analysis (Trainer & Matson 1988). In cases where teeth cannot be successfully extracted or an age confidently determined, the model randomly samples the distribution of known-age animals by sex and assigns an age to that animal for the purpose of the population reconstruction.

Direct estimates of population abundance (Proffitt et al. 2015) will be input into the model when they are available. These periodic field estimates can significantly improve past and future population estimates for individual lion ecoregions. Direct population estimates will be periodically developed for most lion ecoregions following the methods described in Chapter 5.

PopR uses Markov Chain Monte Carlo (MCMC) methods to “fit” IPM population estimates to the available data. MCMC methods estimate parameters in complex models by systematically updating informed prior distributions with information gleaned from field data (e.g. observed harvest). Therefore, they allow us to describe each parameter in terms of a distribution and that distribution’s shape. Parameters described by a narrow and peaked distribution are more precisely estimated than those that are flatter and less peaked.

PopR provides generally acceptable default MCMC settings but also allows users to easily adjust them in the web-based user interface. Typically, 25,000-100,000 MCMC iterations will be required to fit an IPM. **PopR** provides convergence diagnostics in the output report.

IPM USER CONTROLS

Demographic Variation

These settings allow users to decide whether to allow estimates of population vital rates to be drawn from a single distribution (“Constant”) or from a range of all possible distributions that differs every year (“Time Varying”). Biologists should only choose “Time Varying” if they have reason to believe that non-harvest factors (such as weather or prey density) introduce additional volatility in these vital rates that would not have been present during the field research projects from which the “Constant” rate distribution was developed. Research has demonstrated that mountain lion non-harvest survival and reproductive rates are remarkably stable and the “Constant” setting should be considered the default.

Burn-in Length

“Burn-in” is a colloquial term for an initial process that gives the Markov Chain time to approach the solution to the problem by throwing away some less reasonable starting points at the beginning of a Markov Chain Monte Carlo run. Allowing the Burn-in process to establish an equilibrium distribution reduces the number of subsequent MCMC sampling iterations needed to provide an estimate with reasonable certainty. In **PopR**, managers should simply use the default Burn-in Length setting when developing an estimate through the standard user interface.

Markov Chain Monte Carlo (MCMC) Iterations

If the number of MCMC iterations is set too low the uncertainty about an estimate is likely to be misrepresented. In **PopR**, we use the Brooks-Gelman-Rubin (BGR) statistic as an initial assessment and this is the statistic used when automating convergence. The BGR statistic suggests convergence when estimates of Rhat are below 1.1 or more generally close to 1. This statistic is reported under the “Table” tab and highlighted in red when Rhat estimates are above 1.1. The default settings will produce results that are unlikely to change even if run longer, but users should increase the number of MCMC iterations to 15,000 or greater if either Rhat estimates are above 1.1 and/or computing time allows.

Thinning Rate

Thinning tells the sampler to only retain every nth value from the chains. This technique is sometimes used to

reduce autocorrelation in the chains, but comes at the cost of reduced efficiency of the sampler. A more reasonable use of thinning is when hardware limitations are being reached, which typically comes in the form of running out of memory. This will not be an issue in **PopR** and, therefore, the recommended setting for the Thinning slider is **1**.

Automate Convergence

Users may choose to simply check the “Automate Convergence” box below the MCMC sliders menu in the **PopR** interface. Although this option will increase the time necessary to produce an estimate, it will assure that an adequate Burn-in Length and number of MCMC Iterations have been used to produce a statistically sound estimate and error distribution.

Table 22. Default mountain lion vital rates used in Montana’s 2016 Integrated Population Model. Rates are based on field data collected from 263 radio-monitored lions from Montana, Wyoming and Washington.

Parameter	Age	Sex	Mean	SE
Survival	YOY	F	0.5	0.1
Survival	Juvenile	F	0.75	0.1
Survival	SubAdult	F	0.57	0.1
Survival	Adult	F	0.8	0.05
Survival	YOY	M	0.5	0.1
Survival	Juvenile	M	0.75	0.1
Survival	SubAdult	M	0.49	0.1
Survival	Adult	M	0.65	0.05

Pregnancy	SubAdult	F	0.5	0.01
Pregnancy	Adult	F	1	0.01

APPENDIX 3

MOUNTAIN LION DEPREDAATION AND CONTROL GUIDELINES

In accordance with Montana Code Annotated 87-1-201, 87-1-217, 87-1-225, 87-1-301, 87-1-304, 87-3-127, 87-3-128, 87-5-713, 87-5-725, and 87-6-106, Montana Fish, Wildlife and Parks (FWP) and the Fish and Wildlife Commission are both authorized and charged with the duties of protecting persons and personal property from damage and depredation resulting from ingress or attack by wildlife. The goal of the **Mountain Lion Depredation and Control Guidelines** is to minimize damage to property and to prevent public safety problems. For the purpose of these Guidelines, a Public Safety Problem is defined as: Any situation where a FWP employee (or their agent) reasonably determines that a human has been physically injured or killed as a result of contact with a mountain lion, that an attack by a mountain lion has resulted in the loss of livestock or pets, or that the continued presence of a mountain lion poses a threat to human safety.

Any mountain lion that is lethally removed by FWP or its agents must be retained and transferred to the Montana Livestock Loss Board for sale or auction pursuant to MCA 2-15-3110 to 3113 and 87-1-217.

I. DEFINITIONS

The following are definitions designed to standardize the vocabulary used in the investigation and reporting of human/lion conflicts. It is important that the same terms be used to describe the different types of encounters that occur between humans and mountain lions. The definitions presented here are similar to those used in other western states.

Sighting: A visual observation of a mountain lion.

Encounter: An unexpected direct meeting between a human and a mountain lion without incident or the recurrent sighting in close proximity to human development or habitation.

Incident: A conflict between a human and mountain lion that may have serious results (i.e. a mountain lion killing or attempting to kill a pet that must be forced to back down).

Attack: When a human is bodily injured or killed by physical contact by a mountain lion.

Nuisance Lion: A mountain lion involved in encounters and incidents (i.e. pet attacks, continual presence around humans or areas of high human activity, presence near where children are or will be shortly) but is showing no aggression and/or flees when encountered by a human.

Depredation Lion: A mountain lion involved in the killing of livestock.

Aggressive Lion: An individual mountain lion exhibiting aggressive behavior towards humans including a mountain lion that attacks a person without provocation, intentionally approaches humans or fails to retreat when a human takes aggressive actions, or forces a human to take evasive action to avoid attack.

Livestock Depredation: Livestock attacked or killed by a mountain lion.

Conflict: When a human and mountain lion are involved in an encounter, incident or attack, or a mountain lion is determined to be aggressive, a nuisance, or involved in livestock depredation.

II. DOCUMENTATION OF HUMAN-MOUNTAIN LION CONFLICTS

- 1. Each FWP Region is responsible for responding to reports of mountain lion damage to property and human-mountain lion encounters, incidents, or attacks. Regional Supervisors shall ensure the following procedures are used upon FWP employees’ receiving such reports.
 - a. Obtain the name, address, and telephone number of the person making the report, the person receiving the call, and the time and date of the call.
 - b. Record if the conflict involves an Encounter, an Incident, an Attack, or a Livestock Depredation.
 - c. If a Livestock Depredation is reported or suspected, record the number and type of livestock involved and immediately contact the USDA APHIS Wildlife Services agent with responsibility for the area where the incident occurred.
 - d. Record the number of mountain lions involved, its/ their age class (if known), and the date and time of the conflict.
 - e. If the conflict was a human Attack, record the name, sex, and age of the victim, location, and the extent of any injuries. IMMEDIATELY notify both 911 (if that had not already occurred) AND FWP Enforcement Division staff, who will determine whether a Wildlife Human Attack Response Team (WHART) should be convened to initiate a response following WHART Guidelines (Appendix 4).
 - f. Record the location of Encounters, Incidents, and Attacks as specifically as possible, including physical address and/or geospatial coordinates.
 - g. For Encounters, Incidents, or Attacks, record the behavior of the mountain lion and what, if any, action was taken on the part of the person involved.

- h. Record which FWP personnel responded to investigate, the time and date of the response, and what action(s) was taken.

- 2. A description of all reported conflict incidents, including the above information, will be entered into the designated FWP wildlife conflict database as soon as possible following receipt of the report. This record should be updated when the situation is resolved.

III. FWP ACTIONS TO BE TAKEN WHEN HUMAN-MOUNTAIN LION CONFLICTS ARE REPORTED

A FWP employee shall promptly investigate the validity, severity, and details of any reported human-mountain lion conflict. The following guidelines are the minimum actions required of FWP when conflicts are reported. Additional investigation into a conflict, or higher levels of response, will occur at the discretion of the Regional Supervisor and the investigating FWP employee. All interviews and investigations will begin no more than 48 hours after the conflict is reported in accordance with MCA 87-1-225.

<u>CONFLICT</u>	<u>ACTIONS THAT WILL BE TAKEN</u>
Encounter	The reporting party will be contacted and the details of the Encounter (Section II. (1)) will be documented. If the mountain lion involved in the conflict is determined to be a Nuisance Lion, the responding FWP employee and Regional Supervisor may choose to either haze (i.e. using less-than-lethal ammunition or pursued with trained dogs) or lethally remove the mountain lion(s). This decision will depend on the severity of the conflict, location, pattern of habituation, escalation of behavior, or other relevant factors. FWP may also issue a kill permit to the affected landowner. Mountain lions shall not be captured and translocated under any circumstances. Information about the Encounter and FWP’s response will be

	recorded and entered into the FWP wildlife conflict database.			attacking, killing, or threatening to kill a person or livestock. Private citizens may also kill a mountain lion that is in the act of attacking or killing a domestic dog. A person who kills a mountain lion under this statute must notify a FWP employee within 72 hours and surrender the carcass to FWP.
Incident	A FWP employee will conduct an on-site investigation to determine if the mountain lion involved in the conflict is Aggressive. All Aggressive mountain lions will be lethally removed as soon as is practical. If the mountain lion involved in the conflict is determined to be a Nuisance Lion, the responding FWP employee and Regional Supervisor may choose to either haze (i.e. using less-than-lethal ammunition or pursued with trained dogs) or lethally remove the mountain lion(s) depending on the severity of the conflict, location, pattern of habituation, escalation of behavior, or other relevant factors. FWP may also issue a kill permit to the affected landowner. Mountain lions shall not be captured and translocated under any circumstances. Information about the Encounter and FWP's response will be recorded and entered into the FWP wildlife conflict database.			
Depredation		Livestock	If a Livestock Depredation is reported or suspected, the FWP employee will record the number and type of livestock involved, location, livestock owner's contact information, and number of mountain lions involved. The FWP employee will then immediately contact the USDA APHIS Wildlife Services agent with responsibility for the area where the incident occurred and convey that information. That Wildlife Services agent will be responsible for investigating the reported Livestock Depredation and determining the appropriate response.	
Attack	The FWP employee receiving a report of an Attack will record the name, sex, and age of the victim, location, and the extent of any injuries. The employee will IMMEDIATELY notify both 911 (if that had not already occurred) AND FWP Enforcement Division staff, who will determine whether a Wildlife Human Attack Response Team should be convened and to initiate a response following WHART Guidelines. Measures to lethally remove the offending mountain lion(s) will be immediately initiated.		Montana law (MCA 87-6-106) gives private citizens the right to kill, without fear of penalty, any mountain lion attacking, killing, or threatening to kill a person or livestock. Private citizens may also kill a mountain lion that is in the act of attacking or killing a domestic dog. A person who kills a mountain lion under this statute must notify a FWP employee within 72 hours and surrender the carcass to FWP.	
	Montana law (MCA 87-6-106) gives private citizens the right to kill, without fear of penalty, any mountain lion		These Mountain Lion Depredation and Control Guidelines are effective upon Fish and Wildlife Commission's adoption of this Strategy and supersede any previously-adopted versions.	

APPENDIX 4

GUIDELINES FOR RESPONDING TO WILDLIFE ATTACKS THAT RESULT IN HUMAN INJURY OR DEATH: “WHART” GUIDELINES

(Note: attachments and appendices referenced in this section are available from FWP Enforcement Division, upon request)

INTRODUCTION:

This document will provide guidance in the process for handling responses to a wildlife attack that causes human injury or death. In order to provide guidance and standardize the response of FWP personnel, the following guidelines will direct their actions in dealing with wildlife attacks on humans that result in injury and/or death to human victims. It may not be possible to follow these guidelines in every situation.

FIRST RESPONDERS:

An immediate field response is required for any wildlife-caused human injury or death.

In the event of an attack, the responding department employee may take any action necessary that is in the scope of the employee's authority to protect public safety. The following steps should be taken:

1. Secure the safety of the public (ensure proper medical aid for the victim, aid with evacuation of injured or other members of a group, and assist other agencies in removal of the body or victim. Identify the victim's name, address and phone number).
2. Report the incident to 911.
3. Immediately notify the Regional FWP Enforcement Personnel and/or WHART Team personnel.
4. FWP Enforcement personnel confirm as wildlife attack and identify species if possible; if the offending animal is identified the wild animal may

be humanely killed, if possible and depending on the circumstances. Always consult with WHART Team leader and Warden Captain if unsure of actions to be taken with offending animal.

5. If medical, rescue and/or sheriff department personnel arrive on scene before the FWP Incident Commander, advise them about the Wildlife Attack-Victim Kit (Attachment 1 (follow guidelines in Appendix B)) for collecting possible animal saliva stains or hair that might be on the victim prior to cleaning the victim's wounds.

INITIATE THE INCIDENT COMMAND SYSTEM:

- **If a human death or injury has occurred, the Region Warden Captain or other Enforcement designee shall:**
 - Respond to the scene and assume the lead role for FWP.
 - The County Sheriff's Office/Coroner has the initial lead in the investigation of a human death and at first FWP's role is that of assistance.
 - The Warden Captain or Enforcement designee holds FWP Incident Commander responsibility and authority over the scene, locating the animal, its resultant carcass, and any other physical evidence from the attack.
 - The Warden Captain or Enforcement designee will ensure proper collection, transfer, and disposition of all physical evidence and reports.
 - Contact the appropriate landownership, enforcement, and wildlife governing agencies. (refer to Inter Agency Jurisdiction Section)

- **The first warden on the scene shall secure the area in order:**

1. To protect as much of the immediate attack scene as possible, establishing a perimeter as large as possible to avoid contamination or destruction of any evidence.
2. To determine the offending animal and preserve as much on-scene evidence as possible.
3. The area should be excluded from public access by using flagging tape and/or signing stating "Do Not Enter".
4. To preserve the scene, one entry and exit port should be established; only essential personnel should be permitted in the area.

- **If a warden is the first Law Enforcement person on the scene of an attack:**

1. Their first notification should be the County Sheriff's Office.
2. If it appears the incident is an attack only and not a death then FWP will be the lead agency in the incident investigation.
3. If it appears there is a human death the warden should advise the Sheriff's Office that a Coroner will be needed.
4. In the case of a death it should be clear that FWP would at first be in an assisting role to the Sheriff's Office and the Coroner, but FWP's guidelines should be followed as closely as possible.
5. In a human fatality FWP is the lead agency in processing and handling of the offending wildlife, if possible in coordination with County Sheriff/Coroner.
6. Before the victim's body is removed and with

the Coroners assistance it is important to use a Wildlife Attack -Victim Kit (Appendix B and Attachment 1) to collect any forensic evidence possible.

7. The lead investigator must complete Attachment 5 and the investigator will need to work with the Coroner, in the case of a fatality, or the attending physician/medical personnel, in the case of an attack incident victim(s).

- **Once the Warden Captain or the Enforcement designee has been notified of an attack that resulted in human injury or death, he/she must:**

1. Notify the FWP Regional Supervisor (who will notify the Directors Office), FWP Regional Wildlife Management Specialist, and Regional Wildlife Manager.
2. Notify the Regional Information Officer to give him/her initial information; and once notified the Regional Information Officer will become the only contact with the media for FWP in regards to this incident.

- **Upon arrival on scene the Warden Captain or Enforcement designee will set up an area outside the initial crime scene as the Command Post.**

- **The Warden Captain or Enforcement designee will formulate a plan for the systematic investigation of the scene using available manpower and resources.**

- **If applicable, (not all FWP regions utilize this option) activate the Wildlife Human Attack Response Team (WHART).**

- **If applicable, the Enforcement designee, shall assume the role of WHART leader, and shall coordinate and delegate duties before attending the attack site and are responsible for the management of the attack scene from the FWP purview.**

- **WHART Team members will wear fluorescent vests with the Team leader wearing a different color fluorescent vest. These vests will designate the team to other individuals and aid in the safety of the team members while at the scene.**

At this time, with the information available, options should be discussed with the Regional Supervisor and Regional Wildlife Manager on what actions to take regarding the offending animal.

- The suggested approach to a systematic investigation would include:
 1. The Warden Captain, Enforcement designee, or WHART leader will appoint a lead investigator. The lead investigator will conduct the investigation and write a final report of their investigation findings. The lead investigator will be responsible for the investigation at the attack site. The lead investigator should have a team of at least three individuals to assist in evidence collection, securing the scene and photographing and logging of all evidence. One of those members should be the Wildlife Management Specialist or another person that is very experienced in wildlife behavior. The lead investigator shall refer to the “Forensic Guidelines/Wildlife attack Scene Investigation/Management” (Appendix A) as a possible baseline to conduct their investigation and should have attended at least one Wildlife Human Attack Response Training Course. If necessary, the Warden Captain, Enforcement Designee, or WHART leader will appoint a lead person for the potential capture or kill of the offending animal. This person will have to rely on their experience/training and the resources available to locate the offending animal as quickly as possible. If necessary, the animal may be tranquilized, captured, held for DNA testing, or removed from the system. The animal should be shot in the body, to preserve the head. After capture, use the Wildlife Carcass Collection Kit (Appendix C &

Attachment 4) and the Wildlife Attack Kit for Sampling the Animal and Evidence at the Scene (Appendix D & Attachment 4); and the listed Appendices are only suggested guides. The animal should be handled with rubber gloves. The animal must be treated as evidence and be handled to protect the animal’s external body from loss of bloodstains or other such physical evidence originating from the victim. Tape paper or cloth bags over the head and paws. Plug wounds with tight gauze to minimize contamination of the animal with its own blood. Place the carcass inside a protective durable body bag. Avoid dragging the carcass, if possible.

2. The Warden Captain, Enforcement Designee, or WHART leader will designate the task of notifying surrounding residences or persons of the event and safety concerns (usually wildlife biologists will be assigned this task). Land/area closures will have to involve the agencies or owner of the property involved, but it is necessary to restrict public access to the area until the attack scene has been processed and the offending animal captured.
3. The Warden Captain, Enforcement Designee, or WHART leader will notify the FWP Wildlife Lab of the attack and inform them that a potential offending animal will be transported as quickly as possible to the FWP Lab directly for forensic examination/necropsy. A completed Wildlife Attack Response Form and Animal Necropsy form (Appendix E & F) must accompany the animal to the lab.
4. In a fatal incident, the Warden Captain and the Enforcement Designee or WHART leader will meet with the County Coroner/Sheriff, the Regional Supervisor, and the Regional Information Officer to decide how and who will approach the victim’s family to gather information and to provide the family with investigation information.

5. In an attack incident, the Warden Captain, Enforcement Designee, or WHART leader will determine who will meet with the victim and family members in order to obtain investigative information and disseminate investigation information to the victim and family. All interviews will follow Attachment 2 and should be recorded when possible.
6. All media questions should be directed to the Regional Information Officer and the media will not be allowed on scene or at the Command Post.
7. Once evidence has been collected, photographed and logged (Attachment 3) it shall be placed into the custody of the Regional Investigator or designee, who will maintain the evidence and the chain of custody.
8. The Warden Captain, Enforcement designee, or WHART leader will keep a log of the events (Attachment 6) as they occurred at the Command Post and this will be included in the final report.

INFORMATION/MEDIA:

In conjunction with the wildlife attack response guidelines listed above, the following provides direction and guidance in handling the media in the event of an attack on a human by wildlife.

1. The Regional Information Officer (RIO) will be notified immediately in the event of an attack resulting in human injury from big game animals or any wildlife species. Complete and accurate information should be provided to the RIO and inquiries regarding the incident should be handled by the RIO or Regional Supervisor. Media consultation regarding human injuries resulting from federally listed grizzly bears will be coordinated with the USFWS.

Incidents that result from interaction with other

species of wildlife will be managed by personnel within the region where the incident occurred.

County Sheriff/Coroner's offices will coordinate all media regarding status of human deaths. In the event of taking of federally listed species by a public citizen, the USFWS will coordinate all media responses.

2. Department personnel should be helpful and open with the media, but specific questions relating to the incident should be directed to the RIO. It is imperative that appropriate personnel with the region be kept current on developments and all involved receive the same information.
3. A fact sheet and/or statewide press release may be developed with information about the situation and provided upon request to media outlets.
4. If deemed necessary by the RIO, Regional Supervisor, Regional Wildlife Manager, and Warden Captain or Enforcement designee a press conference may be initiated.
5. Appropriate information will be made available to citizens in the vicinity of the incident upon request.

GUIDELINE TRAINING:

The Warden Captain or Enforcement designee is responsible for the distribution of the guidelines and annual training of employees that may be involved in wildlife attack incidents, including first responders.

The Warden Captain or Enforcement designee will assign employees to contact County Sheriff and Search and Rescue teams, and Land Management agencies and offer a review of the guidelines and training.

Employees' responding to attacks incidences, as investigators on the incident shall participate in at least one formal Wildlife Attack Response training each year. The FWP Law Enforcement Program Training Officer will approve these annual Wildlife Human Attack Response training sessions.

INTER-AGENCY JURSDICTION ISSUES:

U.S. Fish and Wildlife Service, Grizzly Bear Recovery Coordinator

U.S. Fish and Wildlife Service Special Agent – based upon their administrative region.

Land Management Agencies, Companies and Emergency Response Teams

The Warden Captain or Enforcement designee will delegate FWP personnel to work in advance with the US Forest Service, BLM, DNRC, Plum Creek Timber, and Search & Rescue Teams to arrange for FWP to enact temporary closures or post warnings to protect the public at a moment’s notice as needed. This advanced contact will include an offer to review the guidelines with all contacts. As soon as possible thereafter, FWP would follow up with the agencies to keep them informed and address any issues or concerns. Search and Rescue Teams and other emergency response units should be kept abreast of special risks on recreational lands in the event that these teams are deployed while the risk of a dangerous bear encounter is elevated.

County Sheriff and Coroner

If an FWP employee is the first on the scene of an attack their first notification should be the County Sheriff’s Office and if it appears there is a human death the employee should advise the Sheriff’s Office that a Coroner will be needed. In the event of a human death, FWP will, at first, be in an assisting role to the Sheriff’s Office and the Coroner, but FWP’s guidelines should be followed as closely as possible. Before the victim’s body is removed and with the Coroners assistance it is important to use a Wildlife Attack -Victim Kit (Attachment 1 & Attachment 5) to collect any forensic evidence possible.

FINAL REPORT:

The Warden Captain, Enforcement designee, or WHART leader is responsible for producing a final report. The report will include a detailed Investigative Summary of the events, how it was resolved, evidence and lab reports, and conclusions. The completed report will be reviewed and released in a timely manner by the Regional Supervisor.

Attachments and WHART Appendices (available from FWP Enforcement Division, upon request)

- Attachment 1** – First Responder Kit Wildlife Attack Human Victim Kit
- Attachment 2** – Interview with Victim and/or witness
- Attachment 3** – Wildlife Attack Scene Evidence Log
- Attachment 4** – Wildlife Attack Animal Evidence Collection Information
- Attachment 5** – Wildlife Attack Victim Evidence Collection Information
- Attachment 6** – Events/Contacts Log

APPENDIX 6

APPLICABLE MONTANA STATUTE AND ADMINISTRATIVE RULES

Montana Code Annotated statutes and Administrative Rules of Montana describing FWP and the Fish & Wildlife Commission's authorities and responsibilities, regulation of the licensed hunting of mountain lions, enumeration of stock grower and personal protection rights, and disclosure of information.

2-15-3110. (Temporary) Livestock loss board - purpose, membership, and qualifications

(1) There is a livestock loss board. The purpose of the board is to administer the programs called for in the Montana gray wolf conservation and management plan, the Montana mountain lion management plan, and the Montana grizzly bear management plan and established in 2-15-3111 through 2-15-3113, with funds provided through the accounts established in 81-1-110, in order to minimize losses caused by wolves, mountain lions, and grizzly bears to livestock producers and to reimburse livestock producers for livestock losses from wolf, mountain lion, and grizzly bear predation.

(2) The board consists of five members, appointed by the governor, as follows:

- (a) three members who are actively involved in the livestock industry and who have knowledge and experience with regard to wildlife impacts or management; and
- (b) two members of the general public who are or have been actively involved in wildlife conservation or wildlife management and who have knowledge and experience with regard to livestock production or management.

(3) The board is designated as a quasi-judicial board for the purposes of 2-15-124. Notwithstanding the provisions of 2-15-124(1), the governor is not required to appoint an attorney to serve as a member of the board.

(4) The board is allocated to the department of livestock for administrative purposes only as provided in 2-15-121.

(5) The board shall adopt rules to implement the provisions of 2-15-3110 through 2-15-3114 and

(6) The board shall prioritize grants for prevention of wolf and grizzly bear predation over those for mountain lion predation.

2-15-3111. Livestock loss reduction program

The livestock loss board shall establish and administer a program to cost-share with individuals or incorporated entities in implementing measures to prevent wolf, mountain lion, and grizzly bear predation on livestock, including:

- (1) eligibility requirements for program participation;
- (2) application procedures for program participation and procedures for awarding grants for wolf, mountain lion, and grizzly bear predation prevention measures, subject to grant priorities and the availability of funds;
- (3) criteria for the selection of projects and program participants, which may include establishment of grant priorities based on factors such as chronic depredation, multiple depredation incidents, single depredation incidents, and potential high-risk geographical or habitat location;
- (4) grant guidelines for prevention measures on public and private lands, including:
 - (a) grant terms that clearly set out the obligations of the livestock producer and that provide for a term of up to 12 months subject to renewal based on availability of funds, satisfaction of program requirements, and prioritization of the project;
 - (b) cost-share for prevention measures, which may be a combination of grant and livestock producer responsibility, payable in cash or in appropriate services, such as labor to install or implement preventive measures, unless the board adjusts the cost-share because of extenuating circumstances related to chronic or multiple depredation; and
 - (c) proactive preventive measures, including but not limited to fencing, fladry, night penning, increased human presence in the form of livestock herders and riders, guard animals, providing hay and dog food, rental of private land or alternative pasture allotments, delayed turnouts, and other preventive measures as information on new or different successful prevention measures becomes available; and
- (5) reporting requirements for program participants to assist in determining the effectiveness of loss reduction relative to each grant."

2-15-3112. Livestock loss mitigation program - definitions

The livestock loss board shall establish and administer a

program to reimburse livestock producers for livestock losses caused by wolves, mountain lions, and grizzly bears, subject to the following provisions:

- (1) The board shall establish eligibility requirements for reimbursement, which must provide that all Montana livestock producers are eligible for coverage for losses by wolves, mountain lions, and grizzly bears to cattle, swine, horses, mules, sheep, goats, llamas, and livestock guard animals on state, federal, and private land and on tribal land that is eligible through agreement pursuant to 2-15-3113(2).
- (2) Confirmed and probable livestock losses must be reimbursed at an amount not to exceed fair market value as determined by the board.
- (3) Other losses may be reimbursed at rates determined by the board.
- (4) A claim process must be established to be used when a livestock producer suffers a livestock loss for which wolves, mountain lions, or grizzly bears may be responsible. The claim process must set out a clear and concise method for documenting and processing claims for reimbursement for livestock losses.
- (5) A process must be established to allow livestock producers to appeal reimbursement decisions. A producer may appeal a staff adjuster's decision by notifying the staff adjuster and the board in writing, stating the reasons for the appeal and providing documentation supporting the appeal. If the documentation is incomplete, the board or a producer may consult with the U.S. department of agriculture wildlife services to complete the documentation. The board may not accept any appeal on the question of whether the loss was or was not a confirmed or probable loss because that final determination lies solely with the U.S. department of agriculture wildlife services and may not be changed by the board. The board shall hold a hearing on the appeal within 90 days of receipt of the written appeal, allowing the staff adjuster and the producer to present their positions. A decision must be rendered by the board within 30 days after the hearing. The producer must be notified in writing of the board's decision.
- (6) As used in this section, the following definitions apply:
 - (a) "Confirmed" means reasonable physical evidence that livestock was actually attacked or killed by a wolf, mountain lion, or grizzly bear, including but not limited to the

presence of bite marks indicative of the spacing of tooth punctures of wolves, mountain lions, or grizzly bears and associated subcutaneous hemorrhaging and tissue damage indicating that the attack occurred while the animal was alive, feeding patterns on the carcass, fresh tracks, scat, hair rubbed off on fences or brush, eyewitness accounts, or other physical evidence that allows a reasonable inference of wolf, mountain lion, or grizzly bear predation on an animal that has been largely consumed.

(b) "Fair market value" means:

- (i) for commercial sheep more than 1 year old, the average price of sheep of similar age and sex paid at the most recent Billings livestock sale ring or other ring as determined by the board;
 - (ii) for commercial lambs, the average market weaning value;
 - (iii) for registered sheep, the average price paid to the specific breeder for sheep of similar age and sex during the past year at public or private sales for that registered breed;
 - (iv) for commercial cattle more than 1 year old, the average price of cattle of similar age and sex paid at the most recent Billings livestock sale ring or other ring as determined by the board;
 - (v) for commercial calves, the average market weaning value;
 - (vi) for registered cattle, the average price paid to the owner for cattle of similar age and sex during the past year at public or private sales for that registered breed;
 - (vii) for other registered livestock, the average price paid to the producer at public or private sales for animals of similar age and sex. A producer may provide documentation that a registered animal has a fair market value in excess of the average price, in which case the board shall seek additional verification of the value of the animal from independent sources. If the board determines that the value of that animal is greater than the average price, then the increased value must be accepted as the fair market value for that animal.
 - (viii) for other livestock, the average price paid at the most recent public auction for the type of animal lost or the replacement price as determined by the board.
- (c) "Probable" means the presence of some evidence to suggest possible predation but a lack of sufficient evidence to clearly confirm predation by a particular species. A

kill may be classified as probable depending on factors including but not limited to recent confirmed predation by the suspected depredating species in the same or a nearby area, recent observation of the livestock by the owner or the owner's employees, and telemetry monitoring data, sightings, howling, or fresh tracks suggesting that the suspected depredating species may have been in the area when the depredation occurred."

2-15-3113. Additional powers and duties of livestock loss board

(1) The livestock loss board shall:

- (a) process claims;
- (b) seek information necessary to ensure that claim documentation is complete;
- (c) provide payments authorized by the board for confirmed and probable livestock losses, along with a written explanation of payment;
- (d) submit monthly and annual reports to the board of livestock summarizing claims and expenditures and the results of action taken on claims and maintain files of all claims received, including supporting documentation;
- (e) provide information to the board of livestock regarding appealed claims and implement any decision by the board;
- (f) prepare the annual budget for the board; and
- (g) provide proper documentation of staff time and expenditures.

(2) The livestock loss board may enter into an agreement with any Montana tribe, if the tribe has adopted a wolf, mountain lion, or grizzly bear management plan for reservation lands that is consistent with the state wolf, mountain lion, or grizzly bear management plan, to provide that tribal lands within reservation boundaries are eligible for mitigation grants pursuant to 2-15-3111 and that livestock losses on tribal lands within reservation boundaries are eligible for reimbursement payments pursuant to 2-15-3112.

(3) The livestock loss board shall:

- (a) coordinate and share information with state, federal, and tribal officials, livestock producers, nongovernmental organizations, and the general public in an effort to reduce livestock losses caused by wolves, mountain lions, and grizzly bears;
- (b) establish an annual budget for the prevention, mitigation, and reimbursement of livestock losses caused

by wolves, mountain lions, and grizzly bears;

(c) perform or contract for the performance of periodic program audits and reviews of program expenditures, including payments to Individuals, incorporated entities, and producers who receive loss reduction grants and reimbursement payments;

(d) adjudicate appeals of claims;

(e) investigate alternative or enhanced funding sources, including possible agreements with public entities and private wildlife or livestock organizations that have active livestock loss reimbursement programs in place;

(f) meet as necessary to conduct business; and

(g) report annually to the governor, the legislature, members of the Montana congressional delegation, the board of livestock, the fish and wildlife commission, and the public regarding results of the programs established in 2-15-3111 through 2-15-3113.

(4) The livestock loss board may sell or auction any carcasses or parts of carcasses from wolves or mountain lions received pursuant to 87-1-217. The proceeds, minus the costs of the sale including the preparation of the carcass or part of the carcass for sale, must be deposited into the livestock loss reduction and mitigation special revenue account established in 81-1-110 and used for the purposes of 2-15-3111 through 2-15-3114."

81-1-110. Livestock loss reduction and mitigation accounts

(1) There are livestock loss reduction and mitigation special revenue accounts administered by the department within the state special revenue fund and the federal special revenue fund established in 17-2-102.

(2)(a) All state proceeds allocated or budgeted for the purposes of 2-15-3110 through 2-15-3114, 81-1-110, and 81-1-111, except those transferred to the account provided for in 81-1-112 [or 81-1-113] or appropriated to the department of livestock, must be deposited in the state special revenue account provided for in subsection (1) of this section.

(b) Money received by the state in the form of gifts, grants, reimbursements, or allocations from any source intended to be used for the purposes of 2-15-3111 through 2-15-3113 must be deposited in the appropriate account provided for in subsection (1) of this section.

(c) All federal funds awarded to the state for compensation for wolf, mountain lion, or grizzly bear depredations on livestock must be deposited in the federal special revenue

account provided for in subsection (1) for the purposes of 2-15-3112.

(3) The livestock loss board may spend funds in the accounts only to carry out the provisions of 2-15-3111 through 2-15-3113.

87-1-201. Powers And Duties

(1) Except as provided in subsection (11), the department shall supervise all the wildlife, fish, game, game and nongame birds, waterfowl, and the game and fur-bearing animals of the state and may implement voluntary programs that encourage hunting access on private lands and that promote harmonious relations between landowners and the hunting public. The department possesses all powers necessary to fulfill the duties prescribed by law and to bring actions in the proper courts of this state for the enforcement of the fish and game laws and the rules adopted by the department.

(2) Except as provided in subsection (11), the department shall enforce all the laws of the state regarding the protection, preservation, management, and propagation of fish, game, fur-bearing animals, and game and nongame birds within the state.

(3) The department has the exclusive power to spend for the protection, preservation, management, and propagation of fish, game, fur-bearing animals, and game and nongame birds all state funds collected or acquired for that purpose, whether arising from state appropriation, licenses, fines, gifts, or otherwise. Money collected or received from the sale of hunting and fishing licenses or permits, from the sale of seized game or hides, from fines or damages collected for violations of the fish and game laws, or from appropriations or received by the department from any other sources is under the control of the department and is available for appropriation to the department.

(4) The department may discharge any appointee or employee of the department for cause at any time.

(5) The department may dispose of all property owned by the state used for the protection, preservation, management, and propagation of fish, game, fur-bearing animals, and game and nongame birds that is of no further value or use to the state and shall turn over the proceeds from the sale to the state treasurer to be credited to the fish and game account in the state special revenue fund.

(6) The department may not issue permits to carry firearms within this state to anyone except regularly appointed officers or wardens.

(7) Except as provided in subsection (11), the department is authorized to make, promulgate, and enforce reasonable rules and regulations not inconsistent with the provisions of Title 87, chapter 2, that in its judgment will accomplish the purpose of chapter 2.

(8) The department is authorized to promulgate rules relative to tagging, possession, or transportation of bear within or outside of the state.

(9) (a) The department shall implement programs that:

(i) manage wildlife, fish, game, and nongame animals in a manner that prevents the need for listing under 87-5-107 or under the federal Endangered Species Act, 16 U.S.C. 1531, et seq.;

(ii) manage listed species, sensitive species, or a species that is a potential candidate for listing under 87-5-107 or under the federal Endangered Species Act, 16 U.S.C. 1531, et seq., in a manner that assists in the maintenance or recovery of those species;

(iii) manage elk, deer, and antelope populations based on habitat estimates determined as provided in 87-1-322 and maintain elk, deer, and antelope population numbers at or below population estimates as provided in 87-1-323. In implementing an elk management plan, the department shall, as necessary to achieve harvest and population objectives, request that land management agencies open public lands and public roads to public access during the big game hunting season.

(iv) in accordance with the forest management plan required by 87-1-622, address fire mitigation, pine beetle infestation, and wildlife habitat enhancement giving priority to forested lands in excess of 50 contiguous acres in any state park, fishing access site, or wildlife management area under the department's jurisdiction.

(b) In maintaining or recovering a listed species, a sensitive species, or a species that is a potential candidate for listing, the department shall seek, to the fullest extent possible, to balance maintenance or recovery of those species with the social and economic impacts of species maintenance or recovery.

(c) Any management plan developed by the department pursuant to this subsection (9) is subject to the requirements of Title 75, chapter 1, part 1.

(d) This subsection (9) does not affect the ownership or possession, as authorized under law, of a privately held listed species, a sensitive species, or a species that is a potential candidate for listing.

(10) The department shall publish an annual game count, estimating to the department's best ability the numbers of each species of game animal, as defined in 87-2-101, in the hunting districts and administrative regions of the state. In preparing the publication, the department may incorporate field observations, hunter reporting statistics, or any other suitable method of determining game numbers. The publication must include an explanation of the basis used in determining the game count.

(11) The department may not regulate the use or possession of firearms, firearm accessories, or ammunition, including the chemical elements of ammunition used for hunting. This does not prevent:

- (a) the restriction of certain hunting seasons to the use of specified hunting arms, such as the establishment of special archery seasons;
- (b) for human safety, the restriction of certain areas to the use of only specified hunting arms, including bows and arrows, traditional handguns, and muzzle loading rifles;
- (c) the restriction of the use of shotguns for the hunting of deer and elk pursuant to 87-6-401(1)(f);
- (d) the regulation of migratory game bird hunting pursuant to 87-3-403; or
- (e) the restriction of the use of rifles for bird hunting pursuant to 87-6-401(1)(g) or (1)(h).

87-1-214. Disclosure Of Information - Legislative Finding - Large Predators

(1) Except for information that is required by law to be reported to state or federal officials, the department may not disclose any information that identifies any person who has lawfully taken a large predator as defined in 87-1-217 during a hunt without the written consent of the person affected. Information that may not be disclosed includes but is not limited to a person's name, address, phone number, date of birth, social security number, and driver's license number.

(2) The legislature finds that the prohibition on disclosure of information pursuant to subsection (1) is necessary to protect an individual's privacy, safety, and welfare.

87-1-217. Policy For Management Of Large Predators - Legislative Intent

(1) In managing large predators, the primary goals of the department, in the order of listed priority, are to:

- (a) protect humans, livestock, and pets;
- (b) preserve and enhance the safety of the public during outdoor recreational and livelihood activities; and
- (c) preserve citizens' opportunities to hunt large game species.

(2) With regard to large predators, it is the intent of the legislature that the specific provisions of this section concerning the management of large predators will control the general supervisory authority of the department regarding the management of all wildlife.

(3) For the management of wolves in accordance with the priorities established in subsection (1), the department may use lethal action to take problem wolves that attack livestock if the state objective for breeding pairs has been met. For the purposes of this subsection, "problem wolves" means any individual wolf or pack of wolves with a history of livestock predation.

(4) The department shall work with the livestock loss board and the United States department of agriculture wildlife services to establish the conditions under which carcasses or parts of carcasses from wolves or mountain lions are retrieved during management activities and when those carcasses or parts of carcasses are made available to the livestock loss board for sale or auction pursuant to 2-15-3113.

(5) The department shall ensure that county commissioners and tribal governments in areas that have identifiable populations of large predators have the opportunity for consultation and coordination with state and federal agencies prior to state and federal policy decisions involving large predators and large game species.

(6) As used in this section:

- (a) "consultation" means to actively provide information to a county or tribal government regarding proposed policy decisions on matters that may have a harmful effect on agricultural production or livestock operations or that may pose a risk to human health or safety in that county or on those tribal lands and to seek information and advice from counties or tribal governments on these matters;
- (b) "large game species" means deer, elk, mountain sheep, moose, antelope, and mountain goats; and

(c) “large predators” means bears, mountain lions, and wolves.

87-1-225. Regulation of Wild Animals Damaging Property - Public Hunting Requirements

(1) Subject to the provisions of subsection (2), a landowner is eligible for game damage assistance under subsection (3) if the landowner:

- (a) allows public hunting during established hunting seasons; or
- (b) does not significantly reduce public hunting through imposed restrictions.

(2) The department may provide game damage assistance when public hunting on a landowner’s property has been denied because of unique or special circumstances that have rendered public hunting inappropriate.

(3) Within 48 hours after receiving a request or complaint from any landholder or person in possession and having charge of any land in the state that wild animals of the state, protected by the fish and game laws and regulations, are doing damage to the property or crops on the property, the department shall investigate and arrange to study the situation with respect to damage and depredation. The department may then decide to open a special season on the game or, if the special season method is not feasible, the department may destroy the animals causing the damage. The department may authorize and grant the holders of the property permission to kill or destroy a specified number of the animals causing the damage. A wild, ferocious animal damaging property or endangering life is not covered by this section.

87-1-271. Annual Lottery Of Hunting Licenses - Proceeds Dedicated To Hunting Access Enhancement

(1) The commission may issue through a lottery one license each year for each of the following:

- (a) deer;
- (b) elk;
- (c) shiras moose;
- (d) mountain sheep;
- (e) mountain goat;
- (f) wild buffalo or bison;
- (g) antelope; and
- (h) mountain lion.

(2) The restriction in 87-2-702(4) that a person who

receives a moose, mountain goat, or mountain sheep special license is not eligible to receive another license for that species for the next 7 years does not apply to a person who receives a license through a lottery conducted pursuant to this section.

(3) The commission shall establish rules regarding:

- (a) the conduct of the lottery authorized in this section;
- (b) the use of licenses issued through the lottery; and
- (c) the price of lottery tickets.

(4) Except as provided in 87-2-903, all proceeds from a lottery conducted pursuant to this section must be used by the department for hunting access enhancement programs and law enforcement.

87-1-301. Powers Of Commission

(1) Except as provided in subsections (7) and (8), the commission:

- (a) shall set the policies for the protection, preservation, management, and propagation of the wildlife, fish, game, furbearers, waterfowl, nongame species, and endangered species of the state and for the fulfillment of all other responsibilities of the department related to fish and wildlife as provided by law;
- (b) shall establish the hunting, fishing, and trapping rules of the department;
- (c) except as provided in 23-1-111 and 87-1-303(3), shall establish the rules of the department governing the use of lands owned or controlled by the department and waters under the jurisdiction of the department;
- (d) must have the power within the department to establish wildlife refuges and bird and game preserves;
- (e) shall approve all acquisitions or transfers by the department of interests in land or water, except as provided in 23-1-111 and 87-1-209(2) and (4);
- (f) except as provided in 23-1-111, shall review and approve the budget of the department prior to its transmittal to the office of budget and program planning;
- (g) except as provided in 23-1-111, shall review and approve construction projects that have an estimated cost of more than \$1,000 but less than \$5,000;
- (h) shall manage elk, deer, and antelope populations based on habitat estimates determined as provided in 87-1-322 and maintain elk, deer, and antelope population numbers at or below population estimates as provided in 87-1-323. In developing or implementing an elk management plan,

the commission shall consider landowner tolerance when deciding whether to restrict elk hunting on surrounding public land in a particular hunting district. As used in this subsection (1)(h), “landowner tolerance” means the written or documented verbal opinion of an affected landowner regarding the impact upon the landowner’s property within the particular hunting district where a restriction on elk hunting on public property is proposed.

(i) shall set the policies for the salvage of antelope, deer, elk, or moose pursuant to 87-3-145; and

(j) shall comply with, adopt policies that comply with, and ensure the department implements in each region the provisions of state wildlife management plans adopted following an environmental review conducted pursuant to Title 75, chapter 1, parts 1 through 3.

(2) The commission may adopt rules regarding the use and type of archery equipment that may be employed for hunting and fishing purposes, taking into account applicable standards as technical innovations in archery equipment change.

(3) The commission may adopt rules regarding the establishment of special licenses or permits, seasons, conditions, programs, or other provisions that the commission considers appropriate to promote or enhance hunting by Montana’s youth and persons with disabilities.

(4) (a) The commission may adopt rules regarding nonresident big game combination licenses to:

(i) separate deer licenses from nonresident elk combination licenses;

(ii) set the fees for the separated deer combination licenses and the elk combination licenses without the deer tag;

(iii) condition the use of the deer licenses; and

(iv) limit the number of licenses sold.

(b) The commission may exercise the rulemaking authority in subsection (4)(a) when it is necessary and appropriate to regulate the harvest by nonresident big game combination license holders:

(i) for the biologically sound management of big game populations of elk, deer, and antelope;

(ii) to control the impacts of those elk, deer, and antelope populations on uses of private property; and

(iii) to ensure that elk, deer, and antelope populations are at a sustainable level as provided in 87-1-321 through 87-1-325.

(5) (a) Subject to the provisions of 87-2-115, the

commission may adopt rules establishing license preference systems to distribute hunting licenses and permits:

(i) giving an applicant who has been unsuccessful for a longer period of time priority over an applicant who has been unsuccessful for a shorter period of time; and

(ii) giving a qualifying landowner a preference in drawings. As used in this subsection (5)(a), “qualifying landowner” means the owner of land that provides some significant habitat benefit for wildlife, as determined by the commission.

(b) The commission shall square the number of points purchased by an applicant per species when conducting drawings for licenses and permits.

(6) (a) The commission may adopt rules to:

(i) limit the number of nonresident mountain lion hunters in designated hunting districts; and

(ii) determine the conditions under which nonresidents may hunt mountain lion in designated hunting districts.

(b) The commission shall consider, but is not limited to consideration of, the following factors:

(i) harvest of lions by resident and nonresident hunters;

(ii) history of quota overruns;

(iii) composition, including age and sex, of the lion harvest;

(iv) historical outfitter use;

(v) conflicts among hunter groups;

(vi) availability of public and private lands; and

(vii) whether restrictions on nonresident hunters are more appropriate than restrictions on all hunters.

(7) The commission may not regulate the use or possession of firearms, firearm accessories, or ammunition, including the chemical elements of ammunition used for hunting.

This does not prevent:

(a) the restriction of certain hunting seasons to the use of specified hunting arms, such as the establishment of special archery seasons;

(b) for human safety, the restriction of certain areas to the use of only specified hunting arms, including bows and arrows, traditional handguns, and muzzle loading rifles;

(c) the restriction of the use of shotguns for the hunting of deer and elk pursuant to 87-6-401(1)(f);

(d) the regulation of migratory game bird hunting pursuant to 87-3-403; or

(e) the restriction of the use of rifles for bird hunting pursuant to 87-6-401(1)(g) or (1)(h).

(8) Pursuant to 23-1-111, the commission does not oversee department activities related to the administration of state parks, primitive parks, state recreational areas, public camping grounds, state historic sites, state monuments, and other heritage and recreational resources, land, and water administered pursuant to Title 23, chapter 1, and Title 23, chapter 2, parts 1, 4, and 9.

87-1-304. Fixing Of Seasons And Bag And Possession Limits

(1) Subject to the provisions of 87-5-302 and subsection (7) of this section, the commission may:

- (a) fix seasons, bag limits, possession limits, and season limits;
- (b) open or close or shorten or lengthen seasons on any species of game, bird, fish, or fur-bearing animal as defined by 87-2-101;
- (c) declare areas open to the hunting of deer, antelope, elk, moose, sheep, goat, mountain lion, bear, wild buffalo or bison, and wolf by persons holding an archery stamp and the required license, permit, or tag and designate times when only bows and arrows may be used to hunt deer, antelope, elk, moose, sheep, goat, mountain lion, bear, wild buffalo or bison, and wolf in those areas;
- (d) subject to the provisions of 87-1-301(7), restrict areas and species to hunting with only specified hunting arms, including bow and arrow, for the reasons of safety or of providing diverse hunting opportunities and experiences; and
- (e) declare areas open to special license holders only and issue special licenses in a limited number when the commission determines, after proper investigation, that a special season is necessary to ensure the maintenance of an adequate supply of game birds, fish, or animals or fur-bearing animals. The commission may declare a special season and issue special licenses when game birds, animals, or fur-bearing animals are causing damage to private property or when a written complaint of damage has been filed with the commission by the owner of that property. In determining to whom special licenses must be issued, the commission may, when more applications are received than the number of animals to be killed, award permits to those chosen under a drawing system. The procedures used for awarding the permits from the drawing system must be determined by the commission.

(2) The commission may adopt rules governing the use of livestock and vehicles by archers during special archery seasons.

(3) Subject to the provisions of 87-5-302 and subsection (7) of this section, the commission may divide the state into fish and game districts and create fish, game, or fur-bearing animal districts throughout the state. The commission may declare a closed season for hunting, fishing, or trapping in any of those districts and later may open those districts to hunting, fishing, or trapping.

(4) The commission may declare a closed season on any species of game, fish, game birds, or fur-bearing animals threatened with undue depletion from any cause. The commission may close any area or district of any stream, public lake, or public water or portions thereof to hunting, trapping, or fishing for limited periods of time when necessary to protect a recently stocked area, district, water, spawning waters, spawn-taking waters, or spawn-taking stations or to prevent the undue depletion of fish, game, fur-bearing animals, game birds, and nongame birds. The commission may open the area or district upon consent of a majority of the property owners affected.

(5) The commission may authorize the director to open or close any special season upon 12 hours' notice to the public.

(6) The commission may declare certain fishing waters closed to fishing except by persons under 15 years of age. The purpose of this subsection is to provide suitable fishing waters for the exclusive use and enjoyment of juveniles under 15 years of age, at times and in areas the commission in its discretion considers advisable and consistent with its policies relating to fishing.

(7) In an area immediately adjacent to a national park, the commission may not:

- (a) prohibit the hunting or trapping of wolves; or
- (b) close the area to wolf hunting or trapping unless a wolf harvest quota established by the commission for that area has been met.

87-2-101. Definitions

As used in Title 87, chapter 3, and this chapter, unless the context clearly indicates otherwise, the following definitions apply:

- (1) "Angling" or "fishing" means to take or the act of a person possessing any instrument, article, or substance for

the purpose of taking fish in any location that a fish might inhabit.

(2) (a) “Bait” means any animal matter, vegetable matter, or natural or artificial scent placed in an area inhabited by wildlife for the purpose of attracting game animals or game birds.

(b) The term does not include:

(i) decoys, silhouettes, or other replicas of wildlife body forms;

(ii) scents used only to mask human odor; or

(iii) types of scents that are approved by the commission for attracting game animals or game birds.

(3) “Fur-bearing animals” means marten or sable, otter, muskrat, fisher, mink, bobcat, lynx, wolverine, northern swift fox, and beaver.

(4) “Game animals” means deer, elk, moose, antelope, caribou, mountain sheep, mountain goat, mountain lion, bear, and wild buffalo.

(5) “Game fish” means all species of the family Salmonidae (chars, trout, salmon, grayling, and whitefish); all species of the genus *Sander* (sandpike or sauger and walleyed pike or yellowpike perch); all species of the genus *Esox* (northern pike, pickerel, and muskellunge); all species of the genus *Micropterus* (bass); all species of the genus *Polyodon* (paddlefish); all species of the family Acipenseridae (sturgeon); all species of the genus *Lota* (burbot or ling); the species *Perca flavescens* (yellow perch); all species of the genus *Pomoxis* (crappie); and the species *Ictalurus punctatus* (channel catfish).

(6) “Hunt” means to pursue, shoot, wound, kill, chase, lure, possess, or capture or the act of a person possessing a weapon, as defined in 45-2-101, or using a dog or a bird of prey for the purpose of shooting, wounding, killing, possessing, or capturing wildlife protected by the laws of this state in any location that wildlife may inhabit, whether or not the wildlife is then or subsequently taken. The term includes an attempt to take by any means, including but not limited to pursuing, shooting, wounding, killing, chasing, luring, possessing, or capturing.

(7) “Migratory game birds” means waterfowl, including wild ducks, wild geese, brant, and swans; cranes, including little brown and sandhill; rails, including coots; Wilson’s snipes or jacksnipes; and mourning doves.

(8) “Nongame wildlife” means any wild mammal, bird, amphibian, reptile, fish, mollusk, crustacean, or other

animal not otherwise legally classified by statute or regulation of this state.

(9) “Open season” means the time during which game birds, game fish, game animals, and fur-bearing animals may be lawfully taken.

(10) “Person” means an individual, association, partnership, or corporation.

(11) “Predatory animals” means coyote, weasel, skunk, and civet cat.

(12) “Trap” means to take or participate in the taking of any wildlife protected by the laws of the state by setting or placing any mechanical device, snare, deadfall, pit, or device intended to take wildlife or to remove wildlife from any of these devices.

(13) “Upland game birds” means sharp-tailed grouse, blue grouse, spruce (Franklin) grouse, prairie chicken, sage hen or sage grouse, ruffed grouse, ring-necked pheasant, Hungarian partridge, ptarmigan, wild turkey, and chukar partridge.

(14) “Wild buffalo” means buffalo or bison that have not been reduced to captivity.

87-2-506. Restrictions On Hunting Licenses

Restrictions on hunting licenses. (1) The department may prescribe by rule the number of hunting licenses to be issued. Any license sold may be restricted to a specific administrative region, hunting district, or other designated area and may specify the species, age, and sex to be taken and the time period for which the license is valid.

(2) When the number of valid resident applications for big game licenses or permits of a single class or type exceeds the number of licenses or permits the department desires to issue in an administrative region, hunting district, or other designated area, then the number of big game licenses or permits issued to nonresident license or permit holders in the region, district, or area may not exceed 10% of the total issued.

(3) Disabled veterans who meet the qualifying criteria provided in 87-2-817(1) must be provided a total of 50 Class A-3 deer A tags, 50 Class A-4 deer B tags, 50 Class B-7 deer A tags, 50 Class B-8 deer B tags, and 50 special antelope licenses annually, which may be used within the administrative region, hunting district, or other designated area of the disabled veteran’s choice, except in a region, district, or area where the number of licenses are less than

the number of applicants, in which case qualifying disabled veterans are eligible for no more than 10% of the total licenses for that region, district, or area.

87-2-507. Class D-1-Nonresident Mountain Lion License

Except as otherwise provided in this chapter, a person who is not a resident, as defined in 87-2-102, but who is 12 years of age or older or who will turn 12 years old before or during the season for which the license is issued may, upon payment of a fee of \$320, receive a Class D-1 license that entitles a holder who is 12 years of age or older to hunt mountain lion and possess the carcass of the mountain lion as authorized by department rules.

87-2-508. Class D-2-Resident Mountain Lion License

Except as otherwise provided in this chapter, a person who is a resident, as defined in 87-2-102, and who is 12 years of age or older or who will turn 12 years old before or during the season for which the license is issued may, upon payment of a fee of \$19, receive a Class D-2 license that entitles a holder who is 12 years of age or older to hunt mountain lion and possess the carcass of the mountain lion as authorized by department rules.

87-2-521. Class D-3-Resident Hound Training License

A person who is a resident, as defined in 87-2-102, and who is 12 years of age or older or who will turn 12 years old before or during the season for which the license is issued, upon payment of a fee of \$5, may receive a Class D-3 hound training license that entitles the holder to use a dog or dogs to aid in pursuing mountain lions or bobcats during the training season established in 87-6-404(4).

87-2-702. Restrictions On Special Licenses - Availability Of Bear And Mountain Lion Licenses

(1) A person who has killed or taken any game animal, except a deer, an elk, or an antelope, during the current license year is not permitted to receive a special license under this chapter to hunt or kill a second game animal of the same species.

(2) The commission may require applicants for special permits authorized by this chapter to obtain a valid big game license for that species for the current year prior to applying for a special permit.

(3) Except as provided in 87-2-815, a person may take only

one grizzly bear in Montana with a license authorized by 87-2-701.

(4) (a) Except as provided in 87-1-271(2) and 87-2-815, a person who receives a moose, mountain goat, or limited mountain sheep license, as authorized by 87-2-701, with the exception of an antlerless moose or an adult ewe game management license issued under 87-2-104, is not eligible to receive another special license for that species for the next 7 years. For the purposes of this subsection (4)(a), “limited mountain sheep license” means a license that is valid for an area in which the number of licenses issued is restricted.

(b) Except as provided in 87-1-271(2) and 87-2-815, a person who takes a mountain sheep using an unlimited mountain sheep license, with the exception of a mountain sheep taken pursuant to an adult ewe license, as authorized by 87-2-701, is not eligible to receive another special license for that species for the next 7 years. For the purposes of this subsection (4)(b), “unlimited mountain sheep license” means a license that is valid for an area in which the number of licenses issued is not restricted.

(5) An application for a wild buffalo or bison license must be made on the same form and is subject to the same license application deadline as the special license for moose, mountain goat, and mountain sheep.

(6) (a) Licenses for spring bear hunts must be available for purchase at department offices after April 15 of any license year. However, a person who purchases a license for a spring bear hunt after April 15 of any license year may not use the license until 24 hours after the license is issued.

(b) Licenses for fall bear hunts must be available for purchase at department offices after August 31 of any license year. However, a person who purchases a license for a fall bear hunt after August 31 of any license year may not use the license until 24 hours after the license is issued.

(7) Licenses for mountain lion hunts must be available for purchase at department offices after August 31 of any license year. However, a person who purchases a license for a mountain lion hunt after August 31 of any license year may not use the license until 5 days after the license is issued.

87-2-806. Taking Fish Or Game For Scientific Purposes

(1) An accredited representative of an accredited school, college, university, or other institution of learning or

of any governmental agency or an individual who is investigating a scientific subject for which collection is necessary, may take, kill, capture, and possess for that purpose any birds, fish, or animals protected by Montana law or department or commission rule if a permit to collect is authorized by the department. Under the provisions of this section, a permittee may take, kill, and capture protected or unprotected birds, fish, or animals in any way that is approved by the department, except by the use of explosives. A permittee may not take, kill, or capture more birds, fish, or animals than are necessary for the investigation. A collection permit may not be given for a species for which a taking is prohibited by statute or rule.

(2) A person who desires to engage in the scientific investigation shall apply to the department for a permit. The department may require the applicant to submit a plan of operations that includes the purpose for the collection, collection methodology to be employed, and the qualifications of the person who will be doing the collecting. The department may set qualifications for persons to whom permits are issued and may place special authorizations or special requirements and limitations on any permit. If the department is satisfied of the good faith and qualifications of the applicant and that the collecting is necessary for a valid purpose, the department:

(a) may issue a permit that must place a time limit on the collections and may place a restriction on the number of birds, fish, or animals to be taken; and

(b) shall require a report of the numbers and species of animals taken by collection areas.

(3) The department may deny a permit if:

(a) the applicant is not qualified to make the scientific investigation;

(b) the proposed collecting is not necessary for the proposed scientific investigation;

(c) the method of collecting is not appropriate;

(d) the proposed collecting may threaten the viability of the species; or

(e) there is no valid reason or need for the proposed scientific investigation.

(4) By December 31 of each year, a permittee shall submit a report to the department that lists the species and numbers of individuals of the species taken and locations from which collections were taken. A permittee who fails to file a required report may not be issued another permit.

(5) The permittee shall pay \$50 for the permit, except that a permittee who is a representative of an accredited school, college, university, or other institution of learning or of any governmental agency is exempt from payment of the fee.

(6) The permittee may not take, have, or capture any other or greater number of birds, fish, or animals than are allowed in the permit.

(7) A representative of an accredited school, college, university, or other institution of learning or an individual permittee who may have various students or associates assisting throughout the year may apply to have a permit issued that includes the individual and the students or associates. The department shall approve the qualifications of a student or an associate and the level of supervision required by the primary permittee. The students or associates, when carrying a copy of the permit, have the same authorizations and restrictions as the primary applicant. The primary applicant shall keep a record of all students or associates listed on the permit and of the dates when each student or associate conducts a collection under the permit. The primary applicant is responsible for the students' or associates' use of the permit or copies of the permit.

87-3-127. Taking Of Stock-killing Animals

(1) Livestock owners, their agents, or employees of the department or a federal agency may use dogs in pursuit of stock-killing black bears, stock-killing mountain lions, and stock-killing bobcats. Other means of taking stock-killing black bears, stock-killing mountain lions, and stock-killing bobcats may be used, except the deadfall.

(2) Traps used in capturing bears must be inspected twice each day with the inspections 12 hours apart.

87-3-128. Exceptions - Department Personnel

The provisions of this chapter relating to methods of herding, driving, capturing, taking, locating, or concentrating of fish, game animals, game birds, or fur-bearing animals do not apply to the department or to any employee thereof while acting within the scope and course of the powers and duties of the department.

87-5-713. Control Of Wildlife Species Permitted To Be Transplanted Or Introduced

Any wildlife species listed in 87-5-714 or approved by the commission for introduction or transplantation may be introduced or transplanted only subject to a plan developed by the department to assure that the population can be controlled if any unforeseen harm should occur.

87-5-725. Notification Of Transplantation Or Introduction Of Wildlife

Notification of transplantation or introduction of wildlife.

(1) When the decision to introduce or transplant a wolf, bear, or mountain lion is made pursuant to this part, the department shall:

(a) provide public notice on its website and, when practical, by personal contact in the general area where the animal is released; and

(b) notify the public through print and broadcast media of the availability of release information on the department's website.

(2) Prior permission from the landowner is required before any animal may be transplanted onto private property.

87-6-106. Lawful Taking To Protect Livestock Or Person

(1) This chapter may not be construed to impose, by implication or otherwise, criminal liability for the taking of wildlife protected by this title if the wildlife is attacking, killing, or threatening to kill a person or livestock. However, for purposes of protecting livestock, a person may not kill or attempt to kill a grizzly bear unless the grizzly bear is in the act of attacking or killing livestock.

(2) A person may kill or attempt to kill a wolf or mountain lion that is in the act of attacking or killing a domestic dog.

(3) A person who, under this section, takes wildlife protected by this title shall notify the department within 72 hours and shall surrender or arrange to surrender the wildlife to the department.

87-6-404. Unlawful Use Of Dog While Hunting

(1) Except as provided in subsections (3) through (6), a person may not:

(a) chase any game animal or fur-bearing animal with a dog; or

(b) purposely, knowingly, or negligently permit a dog to chase, stalk, pursue, attack, or kill a hooved game animal.

If the dog is not under the control of an adult at the time of the violation, the owner of the dog is personally

responsible. A defense that the dog was allowed to run at large by another person is not allowable unless it is shown that at the time of the violation, the dog was running at large without the consent of the owner and that the owner took reasonable precautions to prevent the dog from running at large.

(2) Except as provided in subsection (3)(d), a peace officer, game warden, or other person authorized to enforce the Montana fish and game laws who witnesses a dog chasing, stalking, pursuing, attacking, or killing a hooved game animal may destroy that dog on public land or on private land at the request of the landowner without criminal or civil liability.

(3) A person may:

(a) take game birds during the appropriate open season with the aid of a dog;

(b) hunt mountain lions during the winter open season, as established by the commission, with the aid of a dog or dogs;

(c) hunt bobcats during the trapping season, as established by the commission, with the aid of a dog or dogs; and

(d) use trained or controlled dogs to chase or herd away game animals or fur-bearing animals to protect humans, lawns, gardens, livestock, or agricultural products, including growing crops and stored hay and grain. The dog may not be destroyed pursuant to subsection (2).

(4) A resident who possesses a Class D-3 resident hound training license may pursue mountain lions and bobcats with a dog or dogs during a training season from December 2 of each year to April 14 of the following year.

(5) (a) A person with a valid hunting license issued pursuant to Title 87, chapter 2, may use a dog to track a wounded game animal during an appropriate open season. Any person using a dog in this manner:

(i) shall maintain physical control of the dog at all times by means of a maximum 50-foot lead attached to the dog's collar or harness;

(ii) during the general season, whether handling or accompanying the dog, shall wear hunter orange material pursuant to 87-6-414;

(iii) may carry any weapon allowed by law;

(iv) may dispose of the wounded game animal using any weapon allowed by the valid hunting license; and

(v) shall tag an animal that has been reduced to possession in accordance with 87-6-411.

(b) Dog handlers tracking a wounded game animal with a dog are exempt from licensing requirements under Title 87, chapter 2, as long as they are accompanied by the licensed hunter who wounded the game animal.

(6) Any person or association organized for the protection of game may run field trials at any time upon obtaining written permission from the director.

(7) A person who is convicted of or who forfeits bond or bail after being charged with a violation of this section shall be fined not less than \$50 or more than \$1,000 or be imprisoned in the county detention center for not more than 6 months, or both. In addition, the person, upon conviction or forfeiture of bond or bail, may be subject to forfeiture of any current hunting, fishing, or trapping license issued by this state and the privilege to hunt, fish, and trap in this state or to use state lands, as defined in 77-1-101, for recreational purposes for a period of time set by the court.

(8) A violation of this section may also result in an order to pay restitution pursuant to 87-6-905 through 87-6-907.

87-6-701. Failure To Report Or Tattoo

Failure to report or tattoo. (1) Any bear, wolf, tiger, mountain lion, or coyote that is captured alive to be released later or that is held in captivity for any purpose must be reported to the department within 3 days of the capture or commencement of captivity.

(2) Each animal reported as required in subsection (1) must be permanently tattooed or otherwise permanently identified in a manner that will provide positive individual identification of the animal. No tattoo is required if the animal is subject to a permanent, individual identification process by another state or federal agency.

(3) Any person holding a bear, wolf, tiger, mountain lion, or coyote in captivity shall immediately report to the department any death, escape, release, transfer of custody, or other disposition of the animal.

(4) A person convicted of a violation of this section shall be fined not less than \$50 or more than \$1,000 or be imprisoned in the county detention center for not more than 6 months, or both. In addition, the person, upon conviction or forfeiture of bond or bail, may be subject to forfeiture of any current hunting, fishing, or trapping license issued by this state and the privilege to hunt, fish, or trap in this state or to use state lands, as defined in 77-1-101,

for recreational purposes for a period of time set by the court.

ADMINISTRATIVE RULES OF MONTANA

12.3.105 Limitation On Number Of Hunting Licenses

(1) When the department sets a limitation or quota for the number of hunting licenses to be issued in any hunting district or other designated area, resident applicants shall receive at least 90% of the total hunting licenses to be issued for that game species in that district. When the number of resident applicants totals less than 90% of the quota for that district, all resident applicants shall receive a hunting license for that game species.

(2) The remaining licenses will be issued to the nonresident applicants for that district by drawing.

(3) Any thereafter remaining licenses for that district shall be issued in such manner as the director determines.

12.3.111. License/Permit Prerequisites

(1) Deer. All valid resident conservation license holders and all valid nonresident big game (class B-10) and deer combination (class B-11) license holders may apply for deer permits. However, a holder of a B-11 license obtained through a landowner sponsor can only apply for a deer permit where the permitted area includes the landowner sponsor's property and can only use the permit for hunting on the landowner sponsor's property. All valid conservation license holders may apply for deer B licenses. All nonresident conservation license holders who do not possess a B-10 or B-11 license may apply for a nonresident deer A (B-7) license, if available.

(2) Elk. Only persons who possess a valid resident A-5 elk license or a valid nonresident class B-10 license may apply for a special elk permit or A-7 license.

(3) All valid conservation license holders may apply for moose, sheep, goat, deer B, antelope, black bear, grizzly bear, buffalo, swan, and mountain lion licenses, and turkey permits/licenses. Resident sportsman and nonresident big game combination license holders may not apply for a black bear license if the black bear license is included as part of the combination license.

(4) A nonresident who uses a class B-11 landowner sponsored license in conjunction with a deer permit or a wild turkey license may hunt only on the landowner

sponsor's property. A nonresident who possesses a class B-1 landowner sponsored license and who hunts turkey off the landowner sponsor's property must also hold a class B-1, nonresident bird license valid statewide which is different than the restrictive B-1 license contained in the B-11 license. A nonresident holding both the class B-11 license and the class B-1 license valid statewide may purchase only the number of wild turkey licenses specified on the annual regulations for that season.

12.3.116 Moose, Sheep, And Goat Licenses

- (1) The department shall issue moose, sheep, and goat licenses as described in sections 87-2-701 and 87-2-506 , MCA according to the following policy and procedures:
- (a) Applicants for moose and goat must specify one choice for a hunting district. However, for bighorn sheep, an applicant may specify a second choice.
- (b) Application for unlimited sheep must be postmarked no later than May 1. The deadline may be extended by the department if necessary to provide adequate time for the applicants to apply.
- (2) The following procedure will be used when allocating 10% license opportunities for nonresidents in moose, sheep and goat drawings:
- (a) The total regional license quota, by species and region, will be used to determine 10% nonresident quota.
- (b) Nonresident license allocations will be applied to those hunting districts and season types with a quota of ten or more in the tentative regulations.
- (c) Any remaining license allocation will be put, on a rotating basis, in those districts and season types with a quota of less than ten of the tentative regulations.
- (d) If no district in a region has a quota of ten or more licenses on the tentative regulations, all of the nonresident license authority will be allocated as described in (c).
- (e) If a region has a total quota of less than ten, no nonresident license allocations will be made for that region.

12.3.140 Application For Drawings

- (1) The deadline date for the moose, sheep, and goat special drawings is on or before May 1. The deadline date for elk, deer and antelope special drawings is on or before June 1. All applications for participation in any special permit/license drawing, except drawings under ARM 12.9.801 (damage hunts) provided for by these regulations

must be postmarked by the U.S. Postal Service on or before the deadline date of the current license year, or delivered by private mail service on or before the deadline date; or if personally delivered, received in the Helena Fish, Wildlife and Parks office by 5:00 p.m., on the deadline date of the current license year. If the deadline date for application for any license or drawings, as set by the department, falls on a Sunday or state holiday, that date shall be automatically extended to 5:00 p.m. of the next full work day. The deadline may be extended by the department if necessary to provide adequate time for the applicants to apply.

- (2) The department shall reject an application for any permit/license drawing or for surplus, mountain lion, black bear, trapping, buffalo, or grizzly bear licenses if:
- (a) application is not made on the current year's form provided by the department;
- (b) applicant fails to provide mandatory information on the form;
- (c) applicant fails to sign the application; or
- (d) applicant fails to submit the proper fee. The department will not accept personal checks from nonresidents for nonresident license applications and drawing fees.
- (3) Submittal of more than one application for any one drawing by an individual will disqualify that individual's applications from the drawing for which the multiple applications were submitted.
- (4) No corrections or changes may be made after the department has received the drawing application, except those types that can be made without contacting the applicant. These include:
- (a) adding hunter safety numbers;
- (b) moving valid district choices up to replace invalid choices;
- (c) eliminating species choices on those applications that are short money when the shortfall is the amount for that species; and
- (d) adjusting party applications to insure party consistency.
- (5) Any category of correction made by the department must be applied to all applications. In addition, the department will accept corrections on the applications of those seeking landowner preference. Unless otherwise provided by these rules, all drawings will take place in Helena.
- (6) All applications for participation in buffalo, spring grizzly bear, swan and turkey drawings must be

postmarked by the U.S. Postal Service by the advertised deadline date, or delivered by private mail service on or before the date to the address indicated for the particular drawing which is being applied for.

(7) If an application for any species is rejected by the department pursuant to this rule:

- (a) the application must not be included in the procedure for awarding the permits/licenses applied for;
- (b) the applicant must not be awarded a bonus point for that drawing for that species; and
- (c) the drawing fee, and any bonus point fee, once the application is entered into the drawing, will be retained by the department. Applications not processed in the drawing because of errors will be returned to the applicant with all fees.

12.3.185. Super-tag Hunting Licenses

(1) The department will issue one deer, one elk, one shiras moose, one mountain sheep, one mountain goat, one wild buffalo or bison, one antelope, and one mountain lion hunting license each year through a lottery. These hunting licenses are known as “super-tags.”

(2) For each species, an unlimited number of chances to draw a super-tag will be sold at \$5 per chance. Chances will be sold by license agents as defined in ARM 12.3.201A or through the department authorized web site on the internet. License agents will receive a commission of \$0.50 for each super-tag transaction for a species. A transaction in this case means the purchase of one or more super-tag chances of the same species at one time. Individuals purchasing a ticket through the internet shall pay a convenience fee in accordance with the current internet provider contract.

(3) After the completion of the special license drawing for a species, the department will conduct a computerized drawing selecting randomly the super-tag winner for that species. The department shall issue the appropriate super-tag to the lottery winner.

(4) Only a person legally able to be licensed under current Montana statutes may purchase chances to draw a super-tag or use a super-tag. A person must possess a valid conservation license to be eligible to purchase a chance to draw a super-tag.

(5) The super-tag is valid for the taking of one animal of the species for which it is issued and is valid only for

the current license year. A super-tag may be used in any legally described hunting district open for hunting of that species. A super-tag may be used only during the legal hunting season for the species for which it is issued. The person using the super-tag may use it only during a hunting district’s open season and is subject to all hunting regulations, including special weapons regulations, that apply to a hunting district. However, if a hunting district requires a permit to hunt that species in that district, a super-tag can be used without the special permit.

(6) In the event that a person who drew a license or purchased a license is also drawn for the super-tag for the same species, the person must surrender the license to the department before receiving the super-tag. The department will refund the license fee paid by the winner of the super-tag. The person winning the super-tag shall retain any accumulated bonus points for that species.

(7) The super-tag is a nontransferable license.

APPENDIX 7

MONTANA MOUNTAIN LION IPM MODEL CODE

The Montana Mountain Lion Integrated Population Model was constructed using the statistical programming language R (R Development Core Team 2013).

```
model{
  # Naming
  # Parameter names begin with a capitalized letter

Clint Mecham	Predator Specialist
Dustin Mitchell	Wildlife Biologist

* These members of the Cougar Advisory Group support the majority of the plan but are *of the opinion* that the approved targets allow for the possibility of excessive cougar harvest as judged from the standpoint of the best available science.

Utah Cougar Management Plan V. 3

2015 – 2025

PLAN GOAL: Maintain a healthy cougar population within their current distribution while considering human safety, economic concerns, other wildlife species, and maintaining hunting traditions through 2025.

Definition: A healthy cougar population is one that maintains: 1) a reasonable proportion of older age animals; 2) breeding females; 3) healthy individuals; 4) balance with its natural prey; 5) and genetic variability.

Introduction

The purpose of the Utah Cougar Management Plan is to direct the management of cougars (*Puma concolor*) in accordance with the mission of the Utah Division of Wildlife Resources (Division or DWR) through 2025. An internal review of the plan will be completed 5 years after implementation to ensure that established targets, goals, and objectives meet both management and social needs.

The mission of DWR is:

Serve the people of Utah as trustee and guardian of the state's wildlife

In 1997, the DWR initiated a process to obtain public input on issues and concerns with cougar management. Individuals representing many diverse points of view were invited to form a Cougar Advisory Group. The mission of this group was to aid the Division in preparing a cougar management plan that would gain agreement from diverse groups.

The first version of the Utah Cougar Management Plan (UDWR 1999) resulted from these meetings and was used to direct cougar management efforts from 1999 to 2009. In 2009, the DWR reformed the Cougar Advisory Group to review and update the plan. The group met 8 times between December and May 2010 which resulted in Version 2 (UDWR 2010). After approval of this version several social and management issues led to an emergency meeting of the Wildlife Board. The outcome of the meeting was Version 2.1 of the Utah Cougar Management Plan (UDWR 2011). Subsequently, this version did not fully address the concerns of the public or wildlife managers and the Wildlife Board directed the Division to reform the Cougar Advisory Group with the goal of simplifying the cougar management plan.

This document is version 3 of the Utah Cougar Management Plan which seeks to simplify cougar management and address social and management issues created through previous versions of the plan. The Cougar Advisory Group met 5 times between December and April 2015. The first meeting of the group focused on developing a list of issues and concerns that the group could focus on and address in this document (see Attachment D. Issues and Concerns).

The natural history and ecology of cougars is not included or described in this document because more detailed information on cougar ecology can be found in “Managing Cougars in North America” (WAFWA 2011).

Management History

Cougars were persecuted as vermin in Utah from the time of European settlement in 1847 until 1966. In 1967 the Utah State Legislature changed the status of cougars to that of *protected wildlife*, and since that time they have been considered a game species with established hunting regulations. The first Utah Cougar Management Plan (UDWR 1999) guided cougar management through 2009. Consequently, two additional

versions of the plan were adopted by the Wildlife Board to guide cougar management between 2010 and 2014 (UDWR 2010, 2011).

Cougars use very broad and diverse areas in Utah. The large scale dynamics and interconnectivity of the states cougar populations have been demonstrated through multiple telemetry and GPS radio collar studies (Stoner et al. 2006; 2008; 2013b). Evaluation of the genetic relatedness of cougars in Utah also provides evidence that gene flow occurs over large geographic areas (Sinclair et al. 2001). Cougar harvest has traditionally been controlled in specific geographic areas or hunting units. Version 2 of the management plan sought to tie smaller hunting units to larger home ranges or eco-regions to account for the large spatial scale and source-sink population dynamics (Stoner et al. 2013b; cougar management areas; Figure 1). However, implementation of the eco-region concept limited the ability of the Division to distribute hunters adequately which resulted in heavy hunting pressure and high harvest in easily accessible areas and low to no harvest in areas with limited access.

Figure 1. Cougar Management Areas and Hunting Units

Cougar harvest in Utah has been accomplished using three harvest strategies: harvest objective (quota), limited entry and split (limited entry followed by harvest objective). Under the *harvest objective strategy*, managers prescribe a quota, or number of cougars to be harvested on the unit. An unlimited number of licensed hunters are allowed to hunt during a season which closes as soon as the quota is filled or when the season end date is reached. Hunters are required to check daily to ensure the quota has not been filled. Under the *limited entry strategy*, harvest is managed by limiting the number of hunters on a unit. The number of hunters is determined based upon an expectation of hunting success and the desired harvest size. Individuals are usually selected for hunting on the unit through a random drawing process. Under the *split strategy*, units start the season under the limited entry strategy and then transition to a harvest objective strategy on a set date using the number of limited entry permits that remained unfilled at the time of the transition as the quota for the remaining weeks of the season.

Predator-Prey Relationships

Mule deer are known to be the preferred prey species of cougars (Seidensticker et al. 1973, Ackerman 1982, Mitchell 2013), and in Utah both deer and elk have been identified as primary prey species. In areas where both deer and elk co-exist cougars will usually select deer (Lindzey et al. 1989, Mitchell 2013). Other prey species include lagomorphs, turkey, skunk, fox, porcupines, rodents, bighorn sheep, feral horses, domestic sheep, cattle, bobcat and coyote (Russell 1978, Ackerman et al. 1982, Knopf 2010, Mitchell 2013).

Cougar populations may be limited by prey abundance, availability, and vulnerability (Pierce et al 2000b, Logan and Sweanor 2001), and the relationship between predator and prey is very complex. Much controversy surrounds whether cougar predation can restrict or limit population growth of prey species; the majority of evidence is circumstantial, revolving around observations that deer are preferred prey, high cougar densities, and/or prey populations are declining. Most research indicates that cougars

and predation alone are not a major limiting factor of prey species abundance (Hornocker 1970, Russell 1978, Lindzey et al. 1994, Logan et al. 1996, Pierce et al. 2012). Ballard et al. (2001) reviewed a total of 17 published studies and concluded that deer-predator relationships are confounded by many factors including the relationship of deer to available habitat and carrying capacity. For example in New Mexico, Logan et al. (1996) found that cougar predation was the major cause of mortality in mule deer but that habitat quality was the critical limiting factor. Conversely, when habitat quality was good and the deer population was below carrying capacity, cougar predation did not prevent the deer population from increasing. In Idaho, Hurley et al. (2011) examined mule deer survival in response to removal of both coyote and cougars. Their data indicated that winter severity had the largest influence on population growth rate and predator removal only resulted in slight prey population increases for short term periods.

In contrast, predator-prey dynamics between cougar and bighorn sheep are less ambiguous because most bighorn sheep populations are small in number and isolated in space. Cougar predation on bighorn sheep typically occurs randomly and most often when one individual learns to specialize on bighorn sheep (Logan et al. 1996, Ross et al. 1997, Ernst et al. 2002, Sawyer and Lindzey 2002, Festa-Bianchet. et al. 2006). In a population of desert bighorn sheep radio collared in southeastern Utah, cougar predation was responsible for 53% of radio collared adult mortalities (UDWR unpublished data). In California and Arizona, cougars were implicated in the decline of bighorn sheep populations (Hayes et al. 2000, Schaefer et al. 2000, Kamler et al. 2002), and in Alberta, a single cougar was responsible for killing 9% of the early-winter bighorn sheep population including 26% of the lambs (Ross et al. 1997). Targeted removal of cougar that learn to specialize on bighorn sheep can be beneficial for both cougar and sheep populations (Ernest et al 2002).

The availability and abundance of different prey species in an area as well as the presence of other predators are also factors that may influence prey populations. In some cases a “predator pit” effect can occur when the primary prey experiences a

reduction in numbers but an alternate prey source is available to the predator. This helps artificially keep predator populations high because the predator can switch to other prey, and their population size does not decrease in response to lower availability or preferred prey. The predator can then keep the primary prey species from recovering (Dale et al. 1994, Gassaway 1992).

In 1996 the Utah Wildlife Board approved a Predator Management Policy (DWR Policy No. W1AG-4, last updated in 2006) that authorizes the Division to increase cougar harvest on management units where big game populations are depressed, or where big game has recently been released to establish or supplement new populations. The policy acts under the assumption that predators can slow recovery of prey populations when they are depressed or that a prey population can be kept at a lower density due to predation (Cougar Management Guidelines Working Group 2005). Predator management plans are reviewed by regional staff, the Mammals Program Coordinator, and approved by both the Wildlife Section Chief and DWR Director.

Most predator management plans that affect cougars have been designed to benefit mule deer and/or bighorn sheep. Cougar harvest has been liberalized where mule deer or bighorn sheep are below population management objective, and adult survival is lower than normal under the assumption that large harvests will reduce cougar numbers and hence predation rates, therefore encouraging growth of populations by improving survival. However, drought, habitat alteration and loss and predation all substantially impact big game populations making the effectiveness of predator management plans difficult to evaluate.

This version of the cougar management plan differs from previous versions in that aspects of the Divisions predator management policy are being incorporated into the plan. Mule deer and bighorn sheep population abundance and survival estimates will be used to help determine annual cougar harvest recommendations. This was one of the key social and management issues with previous versions of the Cougar

Management Plan identified through both the public recommendations process and by the Cougar Advisory Group.

In 1999, UDWR implemented a Nuisance Cougar Complaints policy (DWR Policy No. W5WLD-5, last updated in 2006) to provide guidance for reducing damage to private property, reducing public safety concerns, and direction to Division personnel responding to cougar depredation, nuisance, and human safety situations. Any cougar that poses a threat to human safety or preys upon livestock or pets is euthanized, as are sick or injured adult cougars and kittens that are unable to care for themselves in the wild. The Division does not rehabilitate cougars. The only cougars that are captured and translocated are healthy adults and subadults that wander into urban or suburban areas in situations where they have not been aggressive toward humans, pets, or livestock.

Harvest Information

The Division began managing cougar harvests through statewide limited entry hunting in 1990 and increased numbers of permits through 1995-1996. In 1996-1997, additional harvest pressure was added by switching some management units to the harvest objective (quota) system and a record high of 1,496 Permits were sold (Table 1).

Utah's cougar population is monitored through mandatory reporting of all hunter-harvested cougars, cougars that are killed on highways or in accidents and those taken as a result of livestock depredation. Location of kill, sex and age (through a premolar for age estimation) are recorded for every cougar killed and provide the data used to assess management performance in relation to established target values that serve as indicators of population status. Since 1990 cougar mortality in Utah has ranged from 275 (1990) to 666 (1996) and has averaged 421 animals (Figure 2).

	Limited Entry Permits				Harvest Objective Permits			Total Permits	Pursuit Permits

Table 1. Utah Cougar Permits 1990-2013.

Figure 2. Cougar Mortality 1990-2014

Nearly all cougars harvested in Utah are taken with the aid of dogs. An individual hunter is restricted to holding either a limited entry permit or a harvest objective permit per season, and must wait 3 years to reapply once they acquire a limited entry permit. The bag limit is 1 cougar per season. Kittens and females accompanied by young are protected from harvest. The cougar hunting season runs from late November through early June on both limited entry and most harvest objective units. Some units are open year round and some have earlier or later opening dates. Because harvest objective units close as soon as the objective (quota) is reached, hunters must call a toll-free number or check the Division website daily to ensure that the unit they plan to hunt is still open.

Pursuit (chase or no-kill) seasons provide additional recreational opportunities over most of the state. The pursuit season generally follows the hunt season, but specific units have year round pursuit, and a few units are closed to pursuit.

A valuable way to assess cougar population response to hunting is to follow the trend of age structure in harvest over time. The effect hunting has on cougar populations depends on the level of harvest and the sex and age of cougars that are removed. In general transient males are most susceptible to harvest (Barnhurst 1996). Under more intensive harvest pressures fewer juveniles tend to be harvested, followed by a decrease in adult males, and then finally a steady increase in adult females. The longer and more intensive the harvest pressure the more young females will occur in the harvest. This happens because older age animals and males are not available in the population. Likewise, relatively light harvest allows hunters to be more selective and tends to produce more males and older animals (WAFWA 2011).

Most cougar populations can sustain harvest rates of 20-30% of the adult population depending on the age and sex composition of the harvest (Beck et al. 2005). However, recent work in Washington state suggests the natural rate of increase is approximately 12-14% per year (Beausoleil et al. 2013). Large and well connected cougar populations can recover rapidly from over-exploitation (Cougar Management Guidelines 2005) given relaxation from hunting pressure and an adequate influx of immigrants. Cougar populations are most sensitive to the survival or removal of adult females (Martorello and Beusoleil 2003) which may slow or reduce population growth and may eventually lead to population decline (Stoner et al. 2006, Robinson et al. 2008, Cooley et al. 2009*a*, 2009*b*). For example, evaluation of cougar harvest for two different hunting regimes in Utah demonstrated negative impacts on fecundity, density, and age structures when the annual harvest consisted of >30% of the adult population with ≥42% females for periods greater than 3 years (Stoner 2004). Harvest and population data from southern Wyoming indicates that cougar populations can maintain themselves with a harvest comprised of 10-15% adult females (Anderson and Lindzey 2005). For these reasons most states limit female hunting mortality to <50% of the total harvest.

Distribution and Abundance

In Utah cougars occupy 92,696 km² (35,790 mi²) of habitat. Cougars are distributed throughout all available eco-regions (Figure 3) and exhibit a broad habitat tolerance occurring from the semi-arid low-elevation pinion-juniper belt, to the mesic, aspen and conifer dominated forests of the higher mountains and plateaus. Habitat quality varies by ecoregion with the Colorado Plateau and Great Basin containing smaller, naturally fragmented habitats with lower cougar densities, and the mountain ecoregions comprised of relatively large, mesic patches (Stoner et al. 2013a). Residential and commercial development is incrementally reducing cougar distribution through habitat alteration and destruction, particularly along the western border of the Wasatch Mountains in northern and central Utah.

The last statewide cougar population estimates were developed in conjunction with the Utah Cougar Management Plan in 1999 (UDWR 1999). These estimates used extrapolations of cougar densities from published studies in the southwestern United States to: 1) the total area within all management units that comprise cougar range, and 2) the total amount of occupied cougar habitat within Utah. The habitat quality within each management unit was classified as either high, medium or low based on vegetative characteristics, terrain ruggedness (Riley 1998) and prey density. Cougar densities derived from research within Utah, California and New Mexico were associated with each habitat quality level. High quality habitat was assigned a density range of 2.5-3.9 cougars/100 km², medium quality habitat was assigned a density of 1.7-2.5 cougars/100 km² and a density of 0.26-0.52 cougar/100 km² was assigned to low quality habitat. The first statewide population estimate of 2,528-3,936 cougars resulted from summing unit population estimates.

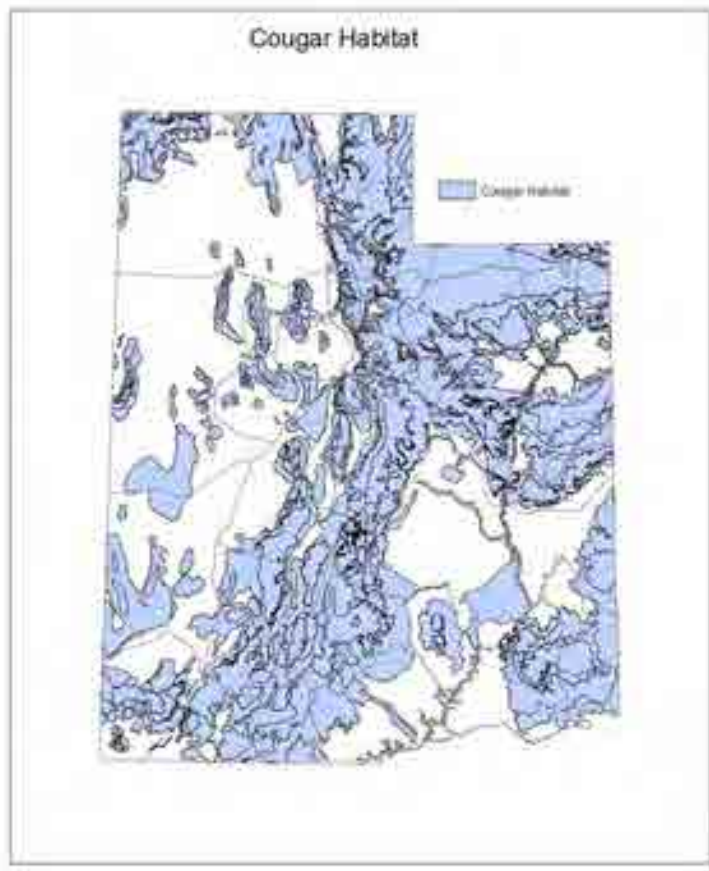

Figure 3. Cougar Habitat in Utah

For comparison, a second estimate of 2,927 cougars statewide was generated based upon mean cougar densities and total occupied cougar habitat within the state. Each management unit's cougar population was estimated by extrapolating the mean cougar density assigned to the unit (based on the respective range indicated above) to the amount of occupied cougar habitat within the unit, and unit estimates were summed to obtain the statewide figure. The two methods produced population estimates that show considerable agreement, but they should be only viewed as general approximations of the statewide cougar population.

Research

Beginning with the observational work of Connolly (1949), up through current investigations of cougar-coyote-mule deer interactions by Julie Young and colleagues,

Utah has a rich history of research on cougar ecology and management. Two topics dominate the literature on the species: predation effects on big game species, and population estimation techniques. In Utah and most western states cougars are often managed from conflicting standpoints. As a predator of mule deer, elk, and bighorn sheep, cougars can be managed as a pest, in which measureable changes in density are desired in order to evaluate the numerical responses of prey. However, when prey survival is not a concern, cougars may be managed as a trophy game species, in which harvest can be fairly conservative. Under both conditions, the ability to estimate and track changes in local abundance is central to effective management.

Cougar research can be subdivided into a few broad topics; natural history, foraging habits and predation, habitat use, and population dynamics. The latter category has received the most attention and involves estimation of abundance, reproduction, and survival rates. In order for management to be effective, a solid understanding of these life history characteristics is essential. The earliest work in Utah was conducted by houndsman and district Predatory Animal and Rodent Control agent, Edward Connolly, who used snow tracking to evaluate predation rates and prey selection in the Wasatch Mountains. These efforts were followed in the 1950s by W. L. Robinette who made further evaluations of food habits by examining the stomach contents of harvested cougars (Robinette et al. 1959). Similarly, these authors used necropsy of females removed through harvest and depredation control to evaluate pregnancy rates, litter size, and breeding seasons (Robinette et al. 1961). Other investigations elaborated on causes of natural mortality (Gashwiler and Robinette 1957). Robinette et al (1977) summarized their findings about cougars and their role in mule deer population dynamics in their study, *The Oak Creek Mule Deer Herd in Utah*. Because of the large sample sizes and relatively simple analyses, some of these papers are still relevant as more recent efforts have only reinforced early findings.

The advent of radio-telemetry in the 1960's facilitated a detailed view of cougar behavior. This tool removed much of the speculation from field work by providing

investigators a means of tracking animals in real time. Telemetry allowed for rigorous measures of home range size, sociality, movement behavior, and predation rates. The work of Lindzey et al. (1989) was the first use of radio-telemetry on cougars in the state. This project was conducted on the Boulder Plateau and adjacent Henry Mountains in southern Utah from 1978 to 1989. By the time this study was initiated, cougars had been classified as a big game species for over a decade, and many of the uncertainties associated with managing a secretive carnivore were apparent. Lindzey focused on applied questions related to cougar predation impacts on deer, elk, and livestock (Ackerman et al. 1984, 1986), population dynamics (Hemker et al. 1984, 1986; Lindzey et al. 1988, 1994), and survey techniques (Van Dyke et al. 1986; Van Sickle and Lindzey 1991, 1992). During the latter years of the study, Lindzey and his students evaluated cougar demographic responses to typical harvesting regimes (Barnhurst and Lindzey 1989; Lindzey et al. 1992; Laing and Lindzey 1993). In 1991 Lindzey published a brief paper on recommendations for future research. Due largely to an inability to accurately census cougars and an increasing concern over human/cougar conflicts the development of reliable survey techniques and evaluation of cougar behaviors in and around urban settings were top among managers concerns.

As the human population in the west have increased and became progressively more urban, societal values have evolved. Along with these changes restructuring of wildlife management policy has changed to include greater public input. Wildlife commissions and advisory boards are the avenue for public input in most western states. Continued debate over abundance, reactions to hunting pressure, and the burgeoning issue of cougars living near people prompted the initiation of Utah's second radio-telemetry effort to examine cougars. This project was led by Dr. Michael Wolfe at Utah State University, and Clint Mecham, a veteran from Lindzey's fieldwork on the Boulder. This new project involved two study areas; one in central Utah on the Fishlake National Forest (Monroe Mountain), and the other due west of the rapidly expanding Salt Lake metro area in the Oquirrh Mountains. The primary difference between these sites was the pattern of land ownership. The Monroe Mountain site was public land and open to

hunting whereas the Oquirrh Mountain site was a patchwork of private properties with restricted access, including large holdings by the Utah Army National Guard and the Kennecott Copper Company. This created a vast region of un-hunted habitat on the edge of an expanding metro area.

Wolfe's study had three central objectives: 1) evaluating cougar enumeration techniques under differing densities, 2) assessing the demographic effects of sustained harvest on cougar demographics, and 3) assessing cougar movement behavior and resource use in an urban-wildland setting. This project ran from 1996 to 2013 and represents the longest comparative study ever conducted on the species. Unlike many diurnally active, herding, or numerically abundant species, there are no robust and widely accepted techniques for cougar enumeration (Choate et al. 2006) and findings from this study underscored the severe limitations imposed by cougar behavior on the development and use of robust survey techniques. Stubbornly small sample sizes, the inherently open nature of cougar populations, and wide dispersal tendencies mean that classic mark-recapture techniques are of limited utility at scales relevant to management (Sinclair et al. 2001, Stoner et al. 2008).

During his Boulder Plateau study, Lindzey addressed the question of harvest effects, but it was an experiment in time on a single study area (before-after). The second objective Wolfe's project was an attempt to replicate the Boulder study in space. The effort here was the first to employ a Before-After-Control-Impact study design in which two populations were monitored simultaneously while varying harvest levels on one site. The Monroe-Oquirrh study lasted 12 years and demonstrated notable demographic differences between populations subjected to different management regimes. Based on these results and combined with the uncertainty of local abundance, Wolfe et al. (2004) recommended statewide implementation of a source-sink type management structure in which known behavioral tendencies, such as male-biased dispersal are used to backfill territories left vacant following harvest. This idea was developed further by Stoner et al.

(2013*a*, 2013*b*), who parameterized cougar dispersal and identified a series of *de facto* refugia, i.e. areas of suitable habitat that exhibit low levels of hunting.

The third objective of this study was pursued by Rieth (2009), Stoner (2011) and Mitchell (2013). These authors looked at habitat use, movement patterns, and predation behavior in the Oquirrh Mountains- a region that encompassed military training, industrial activities, and suburban land-use. Rieth (2009) demonstrated a shift in cougar habitat selection by behavior, which is correlated with time-of-day. Notably, cougars are farthest from human activity during diurnal hours when human activity is highest, and nearest at night when actively hunting. Subsequently, Stoner (2011) found cougars generally avoided areas of predictable human activity, but that aversion was not absolute and some individuals, particularly males and older females with dependent kittens passed occasionally used human dominated landscapes. Mitchell (2013) followed on this work and noted that despite proximity to urban and mixed-use landscapes, cougar depredation on pets and hobby livestock were rare, and that most livestock depredations were on free-ranging cattle in wilderness parts of the study area.

The capstone of the Monroe-Oquirrh cougar project were the evaluations by Wolfe et al. (2015, in review) of commonly used cougar performance measures with respect to known demographics, and an assessment of the degree to which harvest mortality acts in an additive or compensatory manner in cougar populations. These analyses used radio-telemetry data to calibrate catch-per-unit-effort, survival rates, and percent females in the harvest as an index of population performance. Following these efforts the project moved into a second phase in which the Oquirrh Mountain site was closed and remaining resources were directed to a new study objective on the Monroe site. This segment of the project was lead by Julie Young of the National Wildlife Research Center at Utah State University and changed focus from population demographics to the interaction between coyotes, cougars and mule deer. Results are forthcoming.

Objective, Strategies and Management Systems

Outreach and Education

Objective 1:

Increase awareness and appreciation within the general public for the role of cougars in Utah's ecosystems.

Strategy:

1. Determine (survey) the general public's knowledge and attitudes toward the role of cougars in Utah's ecosystems.
2. Implement the new Wild Aware Utah program; an effort generated by the Conservation Outreach Section.

Objective 2:

Educate and increase awareness of the public that utilize cougar habitat about cougar safety.

Strategy:

1. Implement the Wild Aware Utah program.

Objective 3:

Provide educational opportunities to the big game hunting public about the relationship between cougar and prey populations.

Strategies:

1. Develop an educational presentation highlighting cougar-prey interactions geared toward hunting/conservation organizations such as Sportsmen for Fish and Wildlife, Mule Deer Foundation, Rocky Mountain Elk Foundation, Utah Bowman's Association and others.
2. Write articles addressing cougar prey interactions for publication in sportsmen magazines/news letters published by hunting/conservation organizations such as: Sportsmen for Fish

and Wildlife, Mule Deer Foundation, Rocky Mountain Elk Foundation, Utah Bowman's Association and others

3. Explain cougar-prey interactions through radio, television and print media.
4. Periodically assess big game hunter opinions about the effect of cougars on big game populations.

Objective 4:

Educate all cougar hunters on how to determine the age/sex of cougars to increase harvest selectivity and continue to educate Division employees tagging cougars.

Strategies:

1. Continue to publish information about sex and age identification techniques in the Cougar Guidebook and online.
2. Evaluate the effectiveness of the voluntary online orientation course to determine if desired results are being obtained.
3. Modify the harvest reporting form to gather data on effectiveness of orientation course.
4. Survey unsuccessful cougar hunters to gather data on the effectiveness of orientation course.
5. Obtain high quality digital photographs of cougars for sex and age identification education purposes. Examples: treed cougars, lactating females and track and paw sizes for sex and age differentiation.
6. Explore ways to reward hunters for selective harvest.
7. Train Division employees responsible for tagging cougars at least biannually.

Objective 5:

Increase and develop educational opportunities for sportsmen and other user groups prior to the RAC and Board process

Strategy:

1. Hold informational meetings on recommendations prior to taking them through the public process.

Population Management**Objective 1**

Maintain cougar populations within their current statewide distribution in a manner that: 1) recognizes the large geographic and temporal scales at which cougar populations operate, 2) stresses the importance of social structure for long-term viability, 3) directs hunter pressure on a management unit or subunit basis, and 4) manages cougar abundance with respect to their ungulate prey species.

Performance Targets:

- **Primary Target** - Proportion of all females in the harvest < 40% (within a management unit averaged over 3 years)
- **Secondary Target** – Proportion of cougars ≥5 years old in harvest between 15-20% (within a management unit averaged over 3 years)

Strategies (See Attachment A: Cougar Management Tree):

1. Implement the management system based on data for the previous 3 years for all units that mule deer and bighorn sheep triggers are not met as follows:

a. Select limited entry, harvest objective, or split strategy based on the needs of the unit and what type of hunting pressure is appropriate.

b. If proportion of all females in the harvest $<40\%$ then:

1). Proportion of cougars ≥ 5 years old in harvest $\geq 20\%$ then permits/quota may increase.

2). Proportion of cougars ≥ 5 years old in harvest $=15-20\%$ then permits/quota may be maintained or decrease/increase at biologist discretion.

3) Proportion of cougars ≥ 5 years old in harvest $<15\%$ then permits/quota may decrease.

4) Small sample sizes may bias both sex and age data. In these instances the biologist may increase, decrease or maintain permits at their discretion.

c. If proportion of all females in the harvest $\geq 40\%$ then:

1). Decrease permits/quota

Objective 2:

Be responsive to prey population objectives. Manage cougar populations to reduce predation on big game herds that are below objective when cougar predation is considered a potential limiting factor for herd growth or recovery.

Consider development of a predator management plan and implement according to UDWR policy W1AG-4 if annual recommendations are not meeting the needs of the unit.

Performance Targets for units where mule deer or bighorn sheep triggers are met (See Attachment B: Predator Management Tree – Mule Deer):

- **Primary Target** - Proportion of female cougars in the harvest $\geq 40\%$ (within a management area averaged over 3 years)

Strategies:

1. Implement the management system based on data for the previous 3 years for all units that mule deer and bighorn sheep triggers are met as follows:

a. Select limited entry, harvest objective, or split strategy based on the needs of the unit and what type of hunting pressure is appropriate.

b. If mule deer populations are $<90\%$ of unit or subunit objective and conditions listed in 1) or 2) below are met:

1). Adult deer survival on the representative unit $<84\%$ for 2 of the past 3 years and the herd unit is demonstrating a declining population trend (λ is <1) or;

2). Adult deer survival on the representative unit is $<80\%$ in the previous year and the herd unit is demonstrating a declining population trend (λ is <1).

i. Proportion of all females in the harvest $<40\%$ then permits/quota may be increased and may not exceed $+100\%$ of the previous years permits/quota.

ii. Proportion of all females in the harvest $\geq 40\%$ then permits/quota may be maintained at the current level.

c. If mule deer populations are <65% of unit or subunit objective in the previous year.

1). Proportion of all females in the harvest <40% then permits/quota may be increased and may not exceed +100% of the previous years permits/quota.

2). Proportion of all females in the harvest \geq 40% then quota/permits should be maintained at the current level.

d. Bighorn sheep populations where any of the following conditions are met (See Attachment C: Predator Management Bighorn Sheep and Transplants):

1). Population is <90% of unit or subunit objective or;

2). Bighorn sheep population is below viable levels of <125 animals.

i. Proportion of all females in the harvest <40% then permits/quota may be increased and may not exceed +100% of the previous years permits/quota.

ii. Proportion of all females in the harvest \geq 40% then quota/permits may remain the same.

e. When a bighorn sheep, mountain goat, or mule deer transplant or reintroduction will occur in the next year then (See Attachment C: Predator Management Bighorn Sheep and Transplants):

i. Proportion of all females in the harvest <40% then permits/quota may be increased and may not exceed +100% of the previous years permits/quota.

ii. Proportion of all females in the harvest \geq 40% then quota/permits may be maintained.

f. Evaluate ungulate population response annually (based on 3 year average) to determine the need to continue or discontinue predator management direction.

g. When a split unit transitions from limited entry to harvest objective the quota will equal the number of limited entry permits that were not filled during the limited entry season.

h. Bighorn sheep only management areas are management units that don't have an appreciable deer population. On these units the cougar prey base consists primarily of bighorn sheep. These units consist of low elevation primarily snow-free habitat and as a result too few cougars are harvested to analyze relative to performance targets. No quota is assigned to these management units (San Rafael, Kaiparowits, Book Cliffs-Rattlesnake).

i. Offer multiple permits or allow harvest of up to 2 cougars on units/subunits where harvest and access is limited.

j. In special circumstances where it is determined that a cougar may be preying on bighorn sheep the Division may use DWR employees, contract with USDA Wildlife Services (WS), or hire/authorize a contractor outside of the agency to remove the offending animal. The director may authorize removal of depredating cougars as needed.

Chronic Depredation Criteria:

- The depredation is occurring on private land and;
- The depredation has occurred in the same area for 3 consecutive years or 4 out of 5 years and;

- WS has attempted to remove the offending animal(s) but has been unsuccessful.

Strategies:

1. WS increase efforts and/or bring cougar specialists in from other areas to help resolve chronic depredation problems – option to implement after 2 years.
2. Division request that WS continue efforts to remove the offending animal after livestock have left the area, or before they have arrived to resolve chronic depredation problems – option to implement after 2 years.
3. The Division may authorize the livestock owner, an immediate family member or an employee of the owner (not someone specifically hired to take cougar) to remove the offending animal beyond the 72hr period stipulated in Utah Admin Code R657-10-21.

Conditions to the authorization to remove a cougar(s) should include:

- i. The time period during which the cougar(s) can be removed;
- ii. A description of the geographic area from which a cougar(s) can be removed;
- iii. A description of the cougar(s) authorized to be removed (i.e. male, female.....)
- iv. Other relevant conditions

Any cougars removed are considered depredating cougars and are subject to the reporting and possession requirements in the Utah Administrative Code R657-10-21.

4. DWR and WS will work with the houndsmen community to develop a list of houndsmen willing to volunteer their time to help livestock owners resolve chronic depredation issues.

Cougar Research

Objective:

Increase base understanding through continued research designed to address questions relative to cougar management in Utah. Potential research projects are listed below in order of priority.

High Cost Research Priorities (> \$100,000 / Year)

1. Investigate alternative population estimation techniques for cougars using the relationships between primary productions, ungulate abundance, and cougar home range size.
2. Radio collar cougars in bellwether units to obtain adult survival estimates to monitor population trends. Consider using bellwether mule deer units to evaluate efficacy of predator control on mule deer survival.
3. Prey switching in cougars. In multi-prey systems, do cougars switch to alternative prey (e.g. livestock, elk, or feral horses) when mule deer numbers decline? To what extent is cougar predation additive to other sources of mule deer mortality?
4. Cougar habitat use and predation behavior in multi-prey communities (bighorn sheep, mule deer, elk, feral horses). Can we predict bighorn vulnerability to cougar predation in space?
5. Indirect effects of predation risk on foraging behavior of livestock.

Low to Moderate Cost Research Priorities (< \$100,000 / Year)

1. Examining DWR livestock depredation records to evaluate the influence or efficacy of cougar removal on depredation rates. Does cougar removal affect depredation losses in subsequent years? How does depredation risk vary in space, i.e. are there depredation hotspots? What are the demographic patterns in cougar depredation of livestock – cattle vs sheep vs. pets?

2. Examine DWR pet depredation and public safety complaints with respect to cougar management in adjacent units. Are conflicts predicatable in time and space? What are management regimes in units defined by high and low complaints?
3. To what extent can we manipulate the cougar-deer relationship through habitat manipulation? For example can we use prescribed fire to simultaneously increase forage and reduce stalking cover?
4. Evaluate cougar occupancy of military lands, national parks, and other de facto refugia during winter.
5. Modeling the long-term data set to examine cougar population ecology and demographics; population persistence; possible PhD student interested in population models.

Strategies:

1. Continue collaborative research efforts to maximize knowledge base, funding sources and available resources.
2. Explore new funding sources and ways to leverage those resources.
3. Whenever possible use Division employees enrolled in the educational assistance program to conduct research.
4. Work closely with the big game program, and where possible, develop research projects that improve knowledge and understanding of mule deer and cougar.

Re-visit prioritized list every 5 years after implementation to determine if research direction or funding change or new opportunities become available.

Attachment A: Cougar Management Tree

- **Primary Target** - Proportion of all females in the harvest < 40% (within a management area averaged over 3 years)
- **Secondary Target** – Proportion of cougars ≥5 years old in harvest between 15-20% (within a management area averaged over 3 years)

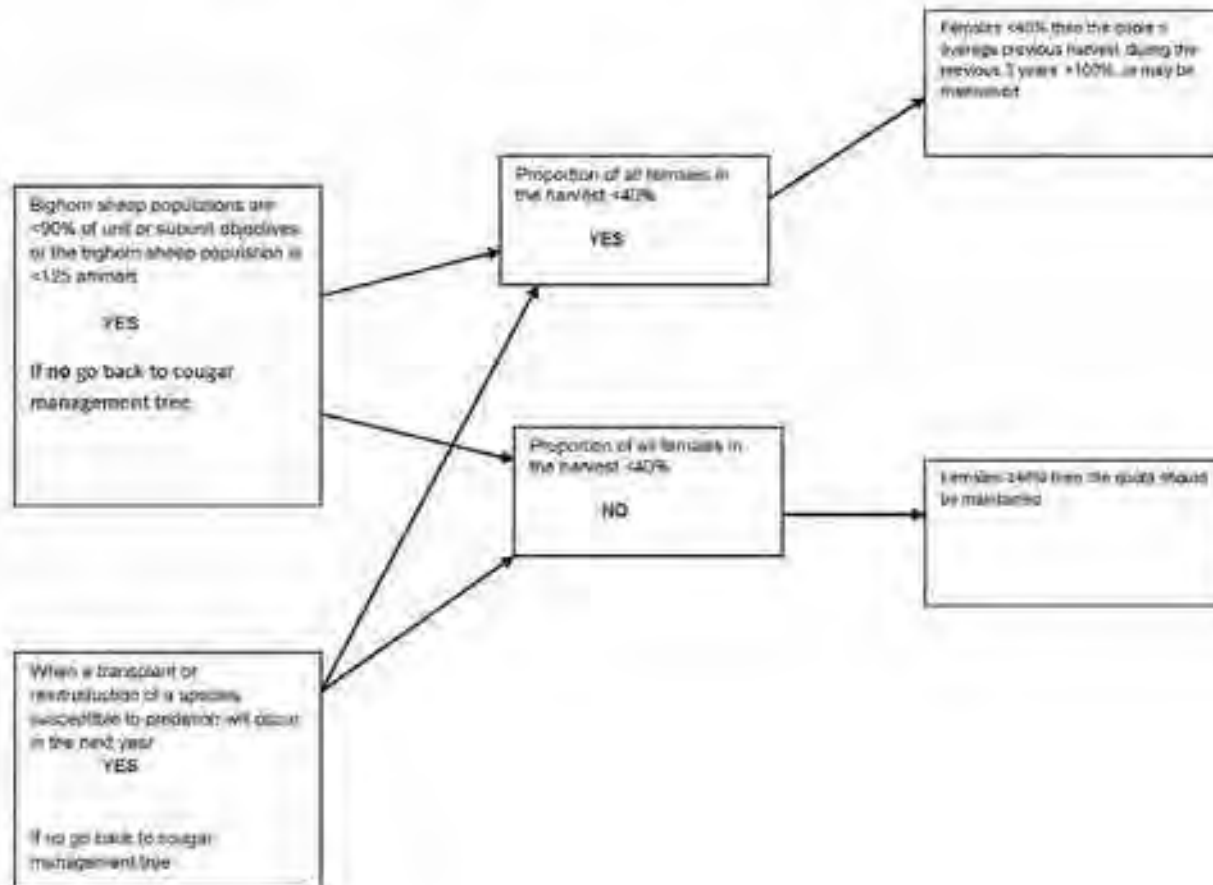

Attachment B: Predator Management Tree - Mule Deer

- Primary Target - Proportion of cougar females in the harvest $\geq 40\%$ (within a management area averaged over 3 years)

Attachment C: Predator Management Tree Bighorn Sheep and Transplants

- **Primary Target** - Proportion of cougar females in the harvest $> 40\%$ (within a management area averaged over 3 years)

Attachment D: Issues and Concerns

During the meetings of the Cougar Advisory Group the following list of issues and concerns were established by the group members. Subsequent meetings focused on discussion, perceptions, and developing, objectives, strategies and management systems to address issues and concerns.

Outreach / Education

- Need to educate the public about the relationship between cougar and prey populations and the need to integrate management of both predator and prey.
- Need to educate hunters on sex/age identification to help protect females and kittens.
- Need to educate the general public about cougars and cougar safety. Especially in communities situated along the urban-wildland interface.
- Need to improve efforts to educate sportsmen and interest groups on our decision making and recommendations process – need more education prior to RAC and Wildlife Board meetings.

Population Management / Harvest Management

- Need tools to solve non-resident issues (pursuit permits, commercial vs recreational).
- Three year plan and recommendation process was too inflexible and didn't allow for responsiveness to depredation, nuisance or population concern responses .
- Need to simplify the management criteria (performance targets).
- Revisit performance criteria.
- Need tools designed to protect all females.
- Female performance targets in previous plan made it difficult to address livestock damage and nuisance using sport harvest .
- Ecoregion/cougar management areas were too broad for hunter management.

- Eco-region/cougar management area quotas shut down entire units too quickly and didn't allow for targeted harvest to address problem areas.
- Need to harvest more females in some situations – female subquota reduces ability to manage in balance with prey.
- Need to recognize the importance of adult males in the social demographic .
- Need to recognize social structure as a predictor of population.
- Need more knowledge and information on source-sink populations.
- Does transition on split units from limited entry to harvest objective lead to over harvest.
- Does harvest objective hunting lead to over harvest of females.
- Hard to encourage harvest in areas that are difficult to hunt.
- Belief that population estimates are too high – need to reevaluate population estimates.
- Would like to require GPS location on all cougar harvests.

Predator Management

- Need to integrate cougar and prey (mule deer and bighorn sheep) management .
- Need to move away from predator management plans.
- Need for evaluation of predator management plans and their effectiveness.
- Need to reduce units under predator management and find a way to balance prey populations with predator populations.
- Need for triggers to be related to livestock depredation, deer survival and populations.

Livestock Depredation

- Need to identify the sex of depredating cougars.
- Develop a way to deal with chronic depredation problems.
- Triggers need to be related to livestock depredation and deer survival.

Research

- Compare ungulate and cougar populations
 - Develop monitoring system to measure deer herd response to variation in cougar abundance on units under predator management
- Explore mark recapture population estimates (DNA sampling).
- Explore cougar survival estimates for population management in relation to representative deer survival units.
- Need more robust population estimates.
- Identify limiting factors for predator management units.

WYOMING GAME & FISH DEPARTMENT

Mountain Lion Management Plan

EXECUTIVE SUMMARY

- The goal of mountain lion management in Wyoming is to sustain mountain lion populations throughout core habitat at varying densities depending on management objectives to provide for recreational/hunting opportunity, maintain ungulate populations at established objectives or in line with current habitat conditions, and minimize mountain lion depredation to pets and livestock and reduce the potential for human injury.
- The intent of this document is to provide guidelines to direct future management efforts for mountain lion populations in Wyoming and not to specifically address local management issues throughout the state; a process that occurs during the 3 year season setting process, when hunt area specific data are presented in the annual mountain lion mortality summaries. The management approach addressed in this document favors an adaptive management process where management objectives are established based on local biological and social conditions and modified/adapted over time relative to management criteria suggesting whether or not objectives have been met, to achieve balance between predator and prey populations, and address changing social factors related to depredation incidents and human-mountain lion interactions.
- Core occupied habitats for adult mountain lions during the winter will be delineated statewide to evaluate impacts from the density of human-caused mountain lion mortalities and to evaluate potential impacts from future development projects. Local (by hunt area) and regional (by Mountain Lion Management Unit-LMU) management objectives will be developed and evaluated based on harvest data. A source-stable-sink adaptive management approach will be applied evaluating (1) density of human-caused mortalities, (2) sex-age composition of mountain lion harvest focusing on relative proportion of adult female harvest, and (3) the relative age of harvested adult females.
- Hunt area management objectives will be based on Regional desires to meet localized situations relative to maintaining low population densities (sink), stable population densities, or to maintain areas with low mountain lion mortality to serve as source areas for mountain lion dispersal into areas experiencing negative population growth (sink areas). Sink management will be applied to maintain low mountain lion densities in areas experiencing high nuisance incidents (livestock depredation, human-lion interactions) and areas where ungulate populations are believed to be depressed primarily due to mountain lion predation; stable management objectives will be implemented to sustain long term hunting opportunity; and source management objectives will be applied to areas where nuisance incidents and predation impacts to prey populations are not an issue. Management objectives at the LMU level will strive for a combination of source, stable, and sink management that will allow for the department to sustain mountain lion populations throughout core habitat at varying densities depending on management objectives.
- Status of representative source areas will be periodically evaluated to verify that these areas are functioning as source areas for mountain lion dispersal using monitoring

techniques that can be reasonably applied relative to Department budget constraints. Success of sink management to address nuisance incidents or predation pressures on ungulate populations will be evaluated over time following the adaptive management process outlined in this plan. Similarly, mountain lion population monitoring criteria will be evaluated and modified as information becomes available addressing the utility of the proposed criteria in defining source, stable, or sink mountain lion habitats.

- Hunting season structure will be based on mountain lion mortality quotas. Mortality quotas will be established for each hunt area, and the hunting season will be closed when the quota has been met. Most of the hunting seasons will run from September 1 through March 31, with the exception of a few hunt areas with chronic livestock depredations. Hunting with hounds will continue to be allowed. Hunters shall present the pelt and skull of harvested mountain lions to Department personnel within 72 hours of harvest so specific data can be recorded. These data will be used to determine the management status, age and sex structure of harvested mountain lions, distribution of mortalities, hunter effort, hunter success, and to account for and set future mortality quotas. Mortality quotas will be established every 3 years to allow sufficient time to reach management objectives and to permit adequate analysis of potential impacts of specific harvest quotas. The process by which these 3-year mortality quotas are set includes annual data analyses and summary by the Trophy Game Section, internal review and recommendations at the regional level, public review of the recommendations, and final approval by the Commission.
- The Department will continue to use a variety of options ranging from no action to lethal removal, which will be assessed on a case-by-case basis, to address mountain lion depredation on domestic livestock and pets and mountain lion/human interactions. All management actions and responses will be documented for future evaluation.
- Adaptive management will be implemented to address short and long-term management needs where appropriate, and additional research efforts will be conducted to address other management priorities as funds become available relative to other Department priorities.
- A previous draft of this management plan was revised based on comments received from 4 peer reviewers and 73 separate public comments. We thank Brad Compton, Idaho Department of Fish and Game, Fred Lindzey, Wyoming Cooperative Fish & Wildlife Research Unit-retired, Ken Logan, Colorado Division of Wildlife, Dale Strickland, Western Ecosystems Technology, Inc, Cheyenne, WY, and members of the public submitting comments for suggestions on improving this management plan. Comments from peer reviewers were evaluated and most have been addressed throughout the revised document. Comments concerning various aspects of the proposed plan (e.g. surveying all mountain lion license holders for hunter effort data, educating hunters about sexing lions in the field, including all human-caused mortality towards quotas, oppose sink management every 3 years, balance source-sink management and reducing the reporting period for harvested lions to 48 hours) were addressed and included in the plan for consideration by the Commission.

- The Department will continue to update and expand, where feasible, information and education efforts across the state including development of a website to educate hunters on sexing mountain lions in the field, and periodically conducting public attitude surveys of Wyoming residents.
- The Department will begin to survey all mountain license holders to enhance the management database.
- All human caused mountain lion mortalities will be counted towards quotas.

MOUNTAIN LION LIFE HISTORY AND ECOLOGY

Distribution

The historic range of the mountain lion was the largest of any terrestrial mammal in the western Hemisphere, with the exception of humans (Logan and Sweanor 2001). The mountain lion continues to range from the southern tip of South America to northern British Columbia (Logan and Sweanor 2001), but were apparently extirpated from the eastern US and Canada, with the exception of southern Florida, by the late 1800s to early 1900s. Between the mid 1960s and the early 1990s, mountain lion populations increased in many western states and they expanded their distribution into some of the mid-western states including Nebraska, South Dakota, and North Dakota likely due to reclassifying mountain lions from unregulated predator status to game animals and the restricted use of pesticides since the early 1970s. Similarly, mountain lions in Wyoming have increased in abundance and distribution and currently occupy most timbered and tall-shrub covered regions statewide. In the early part of the 20th century, efforts to remove mountain lions from many areas of Wyoming caused local extirpations. However, robust populations are currently found in the Black Hills of northeastern Wyoming, the pinyon-juniper country of southwestern Wyoming, and all major mountain ranges throughout the state. This reestablishment of mountain lions throughout Wyoming (and likely throughout much of their former range) is likely due to a shift in management practices and policies that favored increases in numbers and distribution (see Appendix I for mountain lion management history in Wyoming) and habitat conditions favoring increases in some prey abundance (e.g., elk, *Cervus elaphus*, white-tailed deer, *Odocoileus virginianus*).

Dispersal patterns and genetic evidence suggest mountain lion populations throughout most of the western US are well connected (Culver et al. 2000, Sinclair et al. 2001, Anderson et al. 2004). Movements of male mountain lions in excess of 1,000 km have been documented (Thompson and Jenks 2005). These long-range movements provide a very effective means of genetic transfer and population maintenance to mountain lion populations in distant regions. In addition, much of Wyoming's mountain lion habitats are extensions of mountain ranges in other states. This provides excellent connectivity to other habitats, and hence, other mountain lion populations. Overall, gene flow among mountain lion populations in the Central Rocky Mountains suggests this region exists as one large mountain lion population with rapid genetic exchange among suitable habitat patches throughout the region (Anderson et al. 2004).

Habitat Use

The broad geographic distribution of the mountain lion in North America attests to its ability to persist anywhere that provides adequate prey and cover [Cougar Management Guidelines Working Group (CMGWG) 2005]. Previous mountain lion habitat studies in the western US suggest mountain lions select conifer, deciduous timber, riparian, and tall shrub habitat types at mid-high elevations in steep or rugged terrain (Logan and Irwin 1985, Laing 1988, Koehler and Hornocker 1991, Williams et al. 1995, Dickson and Beier 2002). Tall vegetation or rugged terrain sufficient for concealment provides the necessary hiding and stalking cover for securing prey and raising young (CMGWG 2005). Mountain lions may be found in climates ranging from arid regions of desert environments to temperate rainforests of the Pacific Coast. Besides prey

availability, the only biophysical limitations for mountain lions are vast, open areas with little hiding cover and severely cold winter temperatures of northern climates (Pierce and Bleich 2003).

Despite the mountain lions broad distribution and adaptability, human impacts from development and habitat fragmentation can negatively impact mountain lion populations (Beier 1993). Increased construction of roads and homes in mountain lion habitat not only reduces the amount and quality of habitat available to mountain lions and their prey [e.g., deer (*Odocoileus* spp.) and elk (*Cervus* spp.)], but also increases human presence in these areas. Increased human activity ultimately leads to increases in mountain lion/human interactions and mountain lion deaths (CMGWG 2005). Even in sparsely human populated states like Wyoming, where most mountain lion range is still relatively contiguous, subdivisions, new road construction, and oil and gas development may negatively impact mountain lion habitats.

Mountain Lion Social Structure and Reproduction

Social behavior of mountain lions likely evolved to maximize individual survival and reproductive success (Logan and Sweanor 2001). Mountain lions are solitary carnivores exhibiting a polygynous breeding strategy where dominant males typically breed with females that reside within their home range (Murphy 1998). Resident males aggressively defend their territories against male intruders, whereas females allow more overlap, but express mutual avoidance (Lindzey et al. 1989, Ross and Jalkotzy 1992, Logan and Sweanor 2001). Size of female home ranges tend to be large enough to provide sufficient prey for themselves and their young (~50-100 km², 20-40 mi²), while male home ranges tend to be larger (~150-300 km², 60-120 mi²), overlapping several females, apparently to maximize their reproductive success (Murphy 1998). Young females commonly express philopatric behavior (remain in their natal range) upon independence, but males typically disperse from their natal range (Anderson et al. 1992, Ross and Jalkotzy 1992, Lindzey et al. 1994, Logan and Sweanor 2001). Partially due to their solitary and territorial nature and ultimately limited by prey abundance, mountain lion densities are low relative to other large mammals ranging from about 10 independent (>1 year old and self sufficient) mountain lions/1,000 km² (386 mi²) in arid climates (e.g., southern Utah, Lindzey et al. 1989) to about 35 independent mountain lions/1,000 km² in more mesic areas (e.g., the Diablo Range, California, Hopkins 1989, southwest Alberta, Ross and Jalkotzy 1992).

Female mountain lions typically produce their first litter at 2-3 years old (Anderson 1983, Ashman et al. 1983, Logan and Sweanor 2001) and may breed at any time of the year, but exhibit seasonal birth pulses. Data from 7 mountain lion studies in western North America indicate May through October are the peak months for mountain lion parturition (CMGWG 2005). Gestation lasts 82-96 days and mountain lions typically produce 2 to 4 young. The average size of 53 nursing litters documented in New Mexico was 3.0, with 13 (26%) 2-kitten litters, 26 (49%) 3-kitten litters, and 14 (26%) 4-kitten litters (Logan and Sweanor 2001). Other studies reported average litter sizes <6 months old, ranging from 2.2 in Alberta (Ross and Jalkotzy 1992) to 2.9 in Wyoming (Logan et al. 1986). Kittens are usually weaned at 2-3 months and typically remain with the female for 12-18 months before becoming independent (Pierce and Bleich 2003).

Food Habits and Prey Relationships

Mountain lion diets consist primarily of large vertebrate prey species. In much of North America, deer comprise the majority of mountain lion diets (Pierce and Bleich 2003), but other large ungulates such as elk, bighorn sheep (*Ovis canadensis*), moose (*Alces alces*), and pronghorn (*Antilocapra americana*) may also be consumed (Ross and Jalkotzy 1996, Ross et al. 1997, Murphy 1998, Anderson and Lindzey 2003). Although mountain lions primarily subsist on large ungulates, small mammals including porcupines (*Erethizon dorsatum*), lagomorphs (hares and rabbits), ground squirrels (*Spermophilus* spp.), and beavers (*Castor canadensis*) may also supplement mountain lion diets. Mountain lions also occasionally prey on domestic livestock and pets. Sheep and goats are the most commonly killed domestic livestock, but mountain lions also kill cattle, horses, and pets including dogs, and cats (CMGWG 2005).

The mountain lion can be an influential predator on some ungulate populations. Mountain lions were an important source of predation on a bighorn sheep population in Alberta (Ross et al. 1997), and were implicated in the decline of another bighorn population by causing avoidance of high quality forage (Wehausen 1996). Logan and Sweanor (2001) reported that mountain lion predation was the strongest proximate cause limiting a New Mexico mule deer (*O. hemionus*) population by slowing the rate of growth during a population increase phase, and hastening the decline of the population during drought conditions that degraded forage quantity and quality. Mountain lions have annually removed an estimated 15-20% of a mule deer population on the Kaibab Plateau, Arizona (Shaw 1980), 8-12% of a mule deer population on the Uncompahgre Plateau, Colorado (Anderson et al. 1992), and 2-3% of elk and 3-5% of mule deer in the northern Yellowstone Ecosystem (Murphy 1998). Mountain lion predation, however, does not necessarily indicate suppression or regulation of the prey population. Regulation is more likely in systems with multiple prey and multiple predator species. In these situations, predator populations that would normally decrease as their prey populations are reduced, are supported by other, more numerous prey populations (Pierce and Bleich 2003).

The potential impacts of mountain lions on prey populations are largely dependent on the condition of the prey and their habitat. In areas where prey habitat is in good condition, prey body condition will also be greater. Thus, most individuals in the prey population are likely to survive in the absence of predation. In prey populations where individuals are in poor condition due to poor forage quality, however, those individuals are more likely to die regardless of predation. Therefore, mountain lion predation on ungulates in good physical condition is more likely to be *additive* to other causes of mortality. Conversely, mountain lion predation on ungulates in poor physical condition is more likely to be *compensatory* (Logan and Sweanor 2001). In addition, healthy prey populations likely exhibit higher reproductive rates and are more likely to offset predatory regulation by producing more young than are consumed by predators. Ungulate populations exhibiting the characteristics of limitation by predation (Table 1) may benefit from increased mountain lion harvest. Populations limited mainly by habitat conditions will not likely benefit from increases in local mountain lion harvest except during the initial phases of habitat recovery allowing more rapid response of the prey population to improved forage conditions. Additionally, in situations where alternative prey species are lacking, a decline in mountain lion numbers will naturally follow the decrease in the ungulate population regardless of mountain lion harvest levels (CMGWG 2005).

Table 1. Characteristics of ungulate-prey populations regulated by predation and populations regulated by forage conditions (from the Cougar Management Guidelines 2005, page 15).

Life history characteristic	Population size mainly affected by predation ^b	Population size mainly affected by forage
Physical condition of adult females	better	poorer
Pregnancy rate of adult females	higher	lower
Pause in annual production by adult females	less likely	more likely
Yearlings pregnant ^a	usually	seldom
Corpora lutea counts of adult females ^a	higher	lower
Litter size ^a	higher	lower
Age at first reproduction for females	younger	older
Weight of neonates	heavier	lighter
Mortality of young	additive	compensatory
Age at extensive tooth wear	older	younger
Diet quality	higher	lower

^aSome species of ungulates may show limited variability in these characteristics.

^bThese traits will be evident in *any* population far below carrying capacity, even if it experiences *no* predation. The manager should have evidence that predation is a limiting factor before concluding that reducing predation would increase ungulate recruitment.

TRADITIONAL MOUNTAIN LION MANAGEMENT IN WYOMING

Mountain lion management in Wyoming (and throughout its range) has traditionally consisted of more art than science largely due to the secretive nature and naturally low densities typical of this solitary large carnivore and the rugged terrain it typically inhabits. Agencies charged with mountain lion management attempt to address the public's desires, where values vary and sometimes compete between maintaining abundant populations, providing hunting opportunity, and minimizing human conflicts by addressing depredation incidents and potential for mountain lion-human interactions. The goal of mountain lion management in Wyoming is to sustain mountain lion populations throughout suitable mountain lion habitat at varying densities depending on management objectives, and to provide for recreation/hunting opportunity, maintain ungulate populations at established objectives or in line with current habitat conditions, and minimize mountain lion depredation and potential for human injury resulting from mountain lion-human encounters.

Although population estimates have traditionally been lacking, evidence based on professional experience and opinion (i.e., local wildlife biologists, game wardens), increasing mountain lion harvest levels (Appendix II, Fig. II-1), hunter observations, sightings, and nonharvest-human caused mortalities (Appendix II, Fig. II-3) indicate mountain lion populations have increased in Wyoming over the past 30 years. In response to perceived increases in mountain lion numbers, harvest quotas were increased annually during the mid to late 1990s (Appendix II, Fig. II-1). Approaches to how we manage mountain lion populations have changed gradually since 1974 when regulated hunting was first established in Wyoming, including establishment of fall-winter hunting seasons, developing management units and hunt areas to address local management issues, requiring mandatory inspection of harvested mountain lions for annual data collection, and developing total and female harvest quotas to address hunt area management objectives (Appendix I). Traditionally, mountain lion harvest quotas were set based on perceived densities and the history of or potential for human conflicts (e.g., mountain lion-human interactions, depredation incidents, potential impacts to big game species) and adjusted based on perceived mountain population trends relative to annual harvest data, and how quickly quotas were filled each year loosely reflecting hunter effort. Although mountain lion populations in Wyoming increased under this management scheme, this general approach to mountain lion management provided managers with limited ability to determine whether or not management objectives were achieved. The previous Draft Wyoming Mountain Lion Management Plan (1997) identified the lack of data necessary to identify whether or not management objectives have been met and supported research investigating potential methods to adequately monitor mountain lion population responses to varying management prescriptions. Subsequently, mountain lion research was conducted from 1997-2003 (Anderson 2003) to investigate potential approaches for evaluating mountain lion management.

Local and Regional Mountain Lion Management and Annual Data Collection

Wyoming is currently divided into 5 Mountain Lion Management Units (LMU), which are further divided into 29 mountain lion hunt areas (Appendix III). Due to the large size of the West LMU, covering several connected mountain ranges and associated foothill winter mountain lion habitats, the West LMU is divided into 3 separate Data Analysis Units (DAUs) called the Absaroka (hunt areas 19 and 20), Wyoming Range (hunt areas 2, 14, 17, 26, and 29) and Wind River (hunt areas 3, 4, 18 and 28) DAUs (Appendix III). This subdivision provides managers improved capability to monitor the effects of harvest strategies designed to meet potentially different management objectives among these 3 regions.

Mountain lion management units primarily represent connected regions of contiguous mountain lion habitat (i.e., geographic populations), and the smaller hunt areas allow managers to address local management issues while maintaining the overall management objective for the regional population (i.e., within the LMU). The Cougar Management Guidelines Working Group (2005) recently suggested managing mountain lion populations with respect to source-sink dynamics, where source areas would be managed for positive growth and sustain sink areas where management objectives call for reducing mountain lion densities. The current hunt area and management unit structure in Wyoming lends itself well to this concept, where hunt areas within management units can be managed as source and sink subpopulations, depending on local

management issues, and can continue to support desired mountain lion population densities at landscape levels.

Mountain lion management objectives shall be based on ecological data and social conditions to ensure management strategies benefit both the species of concern and the people who are impacted by mountain lion conflicts. Mountain lion mortality data in Wyoming include information obtained annually from harvest or other documented forms of mortality [e.g., natural causes, damage removals, road kills; Appendix II]. Since 1974, hunters have been required to present the pelt and skull of harvested mountain lions to a district game warden, biologist, or a Wyoming Game and Fish Department regional office for registration. Information collected include: harvest date, location (legal description, Universal Transverse Mercator location, and hunt area), sex, lactation history (whether or not females have ever produced young from nipple characteristics; Anderson and Lindzey 2000), estimated age from tooth wear and degree of staining, and collection of teeth for cementum annuli aging, number of days spent hunting, hunting method, and number of mountain lions and mountain lion tracks observed while hunting (Appendix IV). Trainer and Golly (1992) reported 76% agreement ≤ 1 year of annuli ages compared using blind tests of 2 premolars from the same mountain lion ($n = 426$; 92% agreement for lions < 4 years old), and annuli age comparisons of known age mountain lions were 95% accurate (within 1 year; Trainer and Golly 1992:14/15, Anderson 2003:6/6). In addition to mortality data, the Wyoming Game & Fish Department compiles data on mountain lion observations, sign, depredations, human interactions and gauges social concerns through public meetings, hunter surveys, public attitude surveys, and contacts with the public.

Mountain lion mortality data are used to assess: (1) population status, (2) age and sex structure of harvested mountain lions, (3) distribution of mountain lion mortalities, (4) effort expended per mountain lion harvested (Appendix II, Fig. II-2), and (5) to account for and set mortality quotas. Sex and age composition of mountain lion harvests are useful to assess mountain lion population trends (Anderson and Lindzey 2005), and the age of reproductive females can be useful to examine the reproductive potential of mountain lion populations (Stoner 2004, Anderson and Lindzey 2005); populations maintaining older-age females have higher reproductive potential, and thus resiliency, than populations where female survival is reduced. Recording distribution of mountain lion harvest and other human-caused mortalities allows assessment of potential source areas where little or no mountain lion mortality occurs, and sink areas where mountain lion mortalities may be relatively high. Changes in hunter effort may indicate changes in mountain lion densities, assuming the time required to harvest a mountain lion is related to the number of mountain lions in an area. This information is used to establish total and/or female mortality quotas by hunt area every 3 years. Setting mountain lion seasons every 3 years allows sufficient time for management reductions in areas with sufficient hunter access (Anderson and Lindzey 2005) and recovery for previously suppressed populations (Logan and Sweanor 2001, Anderson and Lindzey 2005). The process by which these 3-year mortality quotas are set include (1) annual data analyses and summary by the Trophy Game Section, (2) internal regional review and recommendations provided by each of the 7 Wyoming Game and Fish regions, (3) a public input process, and (4) final hunting season regulations submitted from the regions for action to the Wyoming Game and Fish Commission.

Mountain Lion Hunting Season Structure

Regulation of sport hunting for mountain lions in the western states typically follows 1 of 3 harvest strategies including general seasons, limited entry, and harvest quota systems (CMGWG 2005). General seasons allow unlimited hunting of mountain lions of either sex, and the only restrictions include the number of licenses issued per hunter (typically 1 per season) and timing and length of the hunting season. General seasons provide the highest hunting opportunity, but likely result in uneven hunting pressure (i.e., accessible areas are heavily hunted and inaccessible areas are not) limiting control over harvest level, composition of the harvest, and distribution of the harvest. Limited entry programs limit the number of hunters per hunt area through limited license allocation, using either first come first serve or lottery license sales. This approach is most limiting in terms of hunter opportunity, but can be useful to disperse hunting pressure, control harvest levels, and may increase the opportunity for hunters to be selective (increasing male harvest) in areas where hunting pressure is low. Harvest quota management requires setting a limit on the total harvest and/or number of female mountain lions harvested from an area. The hunting season is closed in an area once the harvest quota has been met. Hunters are required to monitor status of the hunting season by calling a harvest quota hotline. Advantages to the quota management approach are that hunting opportunity remains high and harvest distribution and level can be regulated. Female sub quotas can be used to support a management objective of sustaining harvest levels with reduced impact on the mountain lion population. Potential disadvantages of harvest quota management include the number of hunters per hunt area is unlimited until quotas are filled and harvest quotas may be exceeded if more than 1 mountain lion is harvested the same day the quotas is filled. Harvest quota management has traditionally been used in Wyoming for mountain lion management.

Methods of Mountain Lion Hunting

Mountain lion hunting in Wyoming is accomplished using various hunting methods including opportunistic harvest (spot and stalk) during big game (e.g., elk and deer) seasons, calling mountain lions using predator calls, and tracking and baying mountain lions using trained hunting dogs (i.e., hunting with hounds). The majority of mountain lions harvested annually in Wyoming are taken by hunting with hounds (typically >90%).

Some groups and individuals, both nationally and locally (Gasson and Moody 1995), are concerned about the use of dogs as a hunting method for mountain lions, and some states have recently banned hunting with hounds (e.g., Oregon, Washington). In states where hunting with hounds is not allowed, opportunistic mountain lion hunting (during big game seasons, predator calling) appears comparably successful based on harvest levels observed in Washington and South Dakota. Results from Washington (Martorello and Beausoleil 2003) suggest opportunistic mountain lion hunting is less selective than hunting with hounds and/or female mountain lions are more vulnerable to opportunistic hunting; relative female harvest levels increased from 42% to 59% when hunting with hounds was banned in Washington (mean annual harvest before hound hunting ban = 157 and after hound hunting ban = 199, but harvest rates were not significantly different due to annual harvest variability).

Mountain lion harvest data from Wyoming the past 5 years suggest an average of 32% of successful hound hunters (range = 25-44%; mean total lion harvest from hunting with hounds = 176/year) report being selective while mountain lion hunting and averaged 1.8 days longer in the field than unselective hunters (4.8 days versus 3.0 days). Harvest comparisons indicate on average 49% of unselective and 32% of selective hunters harvest females each year (mean total female harvest = 44%), averaging 9 fewer females and 9 additional males harvested by selective hound hunters in Wyoming annually. Although selectivity reduces female mountain lion harvest, it does not completely explain differences observed between Washington and Wyoming. These differences likely also relate to differences in mountain lion vulnerability between hunting methods.

Anderson (2003) observed that nightly movement distances from Global Positioning System (GPS) data averaged over 3 times longer for male mountain lions than for females (mean end-point distance = 4.6 km versus 1.5 km, 2.9 mi versus 0.9 mi). These longer distance movements expose males more than females to hunting methods where tracking is involved (i.e., hunting with hounds). Opportunistic hunters who do not track mountain lions while hunting are also more likely to harvest the less mobile and more abundant sex (typically females, CMGWG 2005:40) because relative abundance rather than movement patterns drive harvest vulnerability when mountain lions are hunted opportunistically. In addition, hunters with hounds have an increased ability to avoid family groups by detecting young while tracking mountain lions, whereas opportunistic hunters have limited opportunity to determine if young are present.

Potential for Orphaning Young

Because mountain lions can breed and reproduce any time of the year, orphaning of young can result from the harvest of female mountain lions with young. This issue draws emotionally negative responses from some segments of the public and deserves formal appraisal of the potential biological consequences of orphaning young from the harvest of adult female mountain lions. Wyoming law prohibits the harvest of mountain lions accompanied by young, but females may not be accompanied by young while searching for prey (Barnhurst and Lindzey 1989), and therefore may mistakenly be harvested by mountain lion hunters.

Number of mountain lion litters orphaned from hunting can be estimated if data are collected addressing the number of adult females harvested annually. All mountain lions harvested in Wyoming are subjected to mandatory inspection where sex, age, and lactation history data (from nipple characteristics; Anderson and Lindzey 2000) are collected to determine the number of subadult (estimated age <4 years old and have never nursed young) and adult females (nipple characteristics suggest previous lactation and/or estimated age >3 years old) harvested each year. Logan and Sweanor (2001) reported that on average 50% of adult females reproduce and 75% were with dependent young each year. Thus, about 25% of adult females are without young and 25% are with yearlings. Because young may become independent as early as 12 months old or earlier and average dispersal age is about 14-15 months (Anderson et al. 1992, Sweanor et al. 2000), it is unlikely yearling survival is influenced by death of their mother, but survival of young ≤12 months old is likely reduced. Applying these assumptions, timing of female mountain lion harvest, and estimates of monthly birthing rates we can estimate the number of litters orphaned each year due to hunting. Two Wyoming mountain lion studies identified birth

month for 31 litters in north central ($n = 10$, Logan 1983) and southeast Wyoming ($n = 21$, Anderson 2003) and provide estimates of monthly birth rates for Wyoming mountain lions (Table 2). Female harvest of both age classes (non-reproducing subadults, reproductive adults) averaged 88 the past 5 years (fall 2000-spring 2005) and averaged 32 adult females (Table 3). Assuming 50% of reproductive females produce young each year, we estimated about 16 litters ≤ 12 months old may be orphaned in Wyoming annually due to harvest of adult female mountain lions (Table 3).

Table 2. Monthly birth rate from 2 Wyoming mountain lion studies.

Birth month	Number of litters			Monthly birth rate
	North-central, Wyo. ^a	Southeast, Wyo. ^b	Total	
January	0	1	1	0.032
February	0	1	1	0.032
March	0	0	0	0
April	0	1	1	0.032
May	2	1	3	0.097
June	0	4	4	0.129
July	0	3	3	0.097
August	2	5	7	0.226
September	2	1	3	0.097
October	0	1	1	0.032
November	3	2	5	0.161
December	1	1	2	0.065

^aFrom Logan 1983.

^bFrom data collected by Anderson 2003.

This annual estimate of the number of mountain lion litters orphaned in Wyoming may be high (i.e., assumes 50% of adult females are with young when harvested) because our approach ignores the possibility of hunters detecting and passing females with young while hunting, therefore shifting the harvest toward barren females, which likely occurs at some level when mountain lion tracks are followed in the snow while hunting with hounds. To investigate the estimate, we compared the average number of lactating females harvested the past 5 years (mean = 2.6, range 1-3/year) to that expected when compared to data from Tables 2 and 3. Assuming juvenile mountain lions quit nursing at 2-3 months of age (Pierce and Bleich 2003), we would expect annual harvest of lactating females to range somewhere between 2.8 and 4.7. Whether the lower than expected harvest of lactating females is due more to hunter selectivity or reduced

vulnerability resulting from the more sedentary nature of young family groups is unknown but further indicates that some degree of harvest selectivity is occurring.

Based on the estimate of orphaned litters from average adult female mountain lion harvest in Wyoming the past 5 years, 8.7 litters <6 months old and 7.5 litters 6-12 months old (Table 3) would be orphaned in a given year. Survival of orphaned young <6 months old is unlikely, but survival of orphaned young 6-12 months has been documented during at least 3 mountain lion studies (Lindzey et al. 1989, Logan and Sweanor 2001, Anderson 2003) suggesting about 71% survival for this age group; total sample size from the 3 studies was small, resulting in 5 of 7 young orphaned at 6-10 months old surviving. If we assume on average 2 kittens/litter survive to independence (Logan and Sweanor 2001), orphaned young <6 months do not survive, and about 71% of orphaned young 6-12 months old survive, the estimated biological impact to Wyoming mountain lion populations would be an average loss of about 22 juvenile mountain lions annually [$2 \times 8.7 = 17.4$ young <6 months old, $(2 \times 7.5) \times 0.29 = 4.4$ young 6-12 months old]. Based on mountain lion occupancy throughout most timbered and shrub-covered habitats statewide, this level of loss is biologically insignificant, but is still a concern to some segments of the public. If opportunistic hunting increased and hunting with hounds were reduced, we would expect the actual number of young being orphaned to increase because of the apparent increased vulnerability and the higher proportion of females harvested when compared to hunting with hounds (Martorello and Beausoleil 2003).

Table 3. Monthly female mountain lion harvest in Wyoming (recent 5 year average), and estimated number of litters orphaned (<6 months old, 6-12 months old) from adult female harvest.

Month	Mean total female harvest	Mean adult female harvest	Est. mean No. of females w/young ^a	Est. mean No. orphaned litters <6 months old ^b	Est. mean No. orphaned litters 6-12 months old ^c
Sept.	1.4	0.4	0.2	0.12	0.08

Mountain Lion Habitat Management

Mountain lions are habitat generalists evident in their broad geographic distribution ranging throughout a variety of habitat types in much of the western hemisphere. The primary habitat component necessary for mountain lion survival includes some form of hiding cover for securing large prey (e.g., ungulates) and raising young. Although open vegetative communities are rarely used, mountain lions are found in virtually all other vegetation types including coniferous and deciduous forests, woodlands, swamps, savannahs, chaparral, riparian forests, desert canyons and mountains, and semi-arid shrub lands (Hansen 1992). In Wyoming, Logan and Irwin (1985) reported that mountain lions preferred mixed conifer-curleaf mountain mahogany (*Cercocarpus ledifolius*) habitats in rugged terrain, and Anderson et al. (in review) reported mountain lion use of timbered and tall-shrub covered regions occurring near the base of mountain ranges during winter.

Mountain lions, depend on healthy prey populations (e.g., deer, elk), therefore, habitats supporting abundant prey are also important to mountain lion populations. Habitat protection and improvement projects are currently in place for ungulate populations in Wyoming (Wyoming Game & Fish Department 2001), which will undoubtedly benefit mountain lion populations. In addition, Anderson et al. (in review) recently developed a mountain lion habitat model and efforts are currently in place to delineate core winter mountain lion habitat statewide (Fig. 1). Current habitat projects for mountain lion prey species and application of the mountain lion habitat model allow evaluation of potential impacts of proposed development projects to habitats supporting mountain lions and their prey.

Mountain Lion Population Monitoring

Monitoring Mountain Lion Population Trend: Although mountain lion populations have previously been monitored with intensive capture efforts over relatively small areas, reliable and affordable techniques to monitor mountain lion populations for large-scale management programs are lacking. Mountain lion management has traditionally employed harvest strategies with little understanding of the quantitative effect differing harvest levels have on mountain lion population demographics. Sex and age classes of mountain lions exhibit different and relatively predictable movement patterns, where males move longer distances than females and subadults (1-2.5 years old) generally move longer distances than adults (Barnhurst 1986, Anderson 2003). Conceptually, the likelihood of a specific sex or age class of mountain lion being harvested would reflect its relative abundance in the population and its relative vulnerability based on daily movement patterns. In areas where dogs are used to track mountain lions, those mountain lions that typically move longer distances would most likely be detected first (males/subadults). The least vulnerable individuals (adult females) should become prominent in the harvest only after the population has been reduced in size by removal of more vulnerable/available mountain lions. Anderson and Lindzey (2005) tested these predictions applying varying levels of hunter harvest and found harvest composition to be predominantly subadults for a high-density population with low harvest levels, shift to adult males as harvest levels increased, and then a shift from adult males to adult females with continued high harvest as the population declined. When harvest levels were reduced, composition of the harvest returned to primarily subadults. The male segment of the reduced population recovered within 2 years primarily due to male immigration

Figure 1. Wyoming mountain lion winter habitat based on model predictions for those portions of Wyoming with suitable vegetation data available for analyses (Anderson et al. in review). Winter mountain lion habitat represents areas suitable for resident adult mountain lions and not necessarily transient subadults (i.e., core mountain lion habitat). Background represents USGS 1:250,000 scale maps. Mountain lion habitat analyses will be completed for areas outside the habitat data analysis area (e.g., northeast and southwest Wyoming) when sufficient vegetation data layers are developed for those regions of the state.

from other populations and the female segment within 3 years from an increased number of females producing young within the population (Anderson and Lindzey 2005).

We compared harvest composition and age of harvested adult females from the Snowy Range (Fig. 2; Anderson and Lindzey 2005) to 2 other areas in Wyoming (Fig. 3; Star Valley and the Laramie Range) where management objectives called for increasing harvest levels to reduce mountain lion populations (i.e., where comparable data were available). We then applied the

Snowy Range harvest composition, total harvest, harvest density, and adult female age

Snowy Range pre & post-hunting season cougar population estimates

Figure 2. Sex/age composition of mountain lion harvest (pie charts), total harvest, harvest density (mountain lions/1,000 km²), and mean annuli age of adult females (top bar graph) and pre and post-hunting season mountain lion population estimates (bottom bar graph; Anderson and Lindzey 2005) from the Snowy Range, Wyoming, 1998-2003. Numbers above adult female age represent sample size. Note initial high harvest density (>12 mountain lions/1,000 km²), decline in adult male harvest, increase in adult female harvest, and decline in age of harvested adult females as the population decreased in size. Also note low harvest densities (<5 mountain lions/1,000 km²) and low adult female harvest levels during population increase.

Figure 3. Sex/age composition of mountain lion harvest (pie charts), total harvest, harvest density (mountain lions/1,000 km²), and mean age of adult females harvested from Star Valley (hunt area 26), Wyoming, 1999-2004 (top bar graph) and from the Laramie Range (hunt areas 6 and 27), Wyoming, 1996-2001 (bottom bar graph). Numbers above adult female age represent sample size. Mountain lion harvest was increased >40% during the first harvest year in each area to achieve the management objective of reducing mountain lion populations.

Wyoming mountain lion habitat model (Anderson et al. in review; Fig. 1) to evaluate harvest densities among areas. The Snowy Range mountain lion population declined about 33% (fall population estimates) following a harvest density of 12.3 mountain lions/1,000 km² (386 mi²; 1998/99 harvest year) and continued to decline another 13% following a harvest density of 8.4 mountain lions/1,000 km² (386 mi²; 1999/00 harvest year). Harvest composition shifted from primarily adult males to adult females and mean annuli age of harvested adult females declined from 6.3 to 3.6 years old as the population declined (Fig. 2). The Snowy Range mountain lion population recovered to previous levels following a 3-year period where harvest densities were between 3.0-4.0 mountain lions/1,000 km² (386 mi²) and harvest composition consisted primarily of subadults, buffering the adult female segment of the population during recovery (2000/01-2002/03 harvest years; Fig. 2). We noted similar progressions in harvest density, harvest composition, and mean age of harvested adult females for Star Valley and the Laramie Range (Fig. 3), except that harvest composition shifting from adult males to adult females was more gradual in Star Valley. Harvest densities remained moderate (typically between 6-7 mountain lions/1,000 km²) following initial high harvest densities (>10/1,000 km²) in both areas, and older age females (>5 years old) were not evident in the harvest until the second year of high harvest density in the Laramie Range. The more gradual increase in adult female harvest for Star Valley is likely due to this area being more connected to adjacent mountain lion habitat than the Snowy or Laramie ranges (i.e., more resilient to mountain lion harvest allowing animals from adjacent areas to replace harvested animals). Based on relatively high adult female harvest and intermediate harvest densities (Fig. 3), Star Valley and Laramie Range mountain lion populations were likely maintained at low-moderate densities during the periods examined.

Population Estimation Methods: Obtaining accurate and precise estimates of mountain lion population size for each managed population can be logistically and financially challenging, limiting application of estimation methods to relatively small areas every several years. Methods that have been evaluated or hold promise for estimating mountain lion populations for large-scale management programs include ground-based track surveys, sampling mountain lion tracks during helicopter surveys (i.e., helicopter probability sampling; Van Sickle and Lindzey 1991), and DNA or camera-based mark-recapture efforts. Application of DNA or camera-based mark-recapture methods to estimate mountain lion populations is currently limited because there does not appear to be a reliable attractant for luring mountain lions into hair collection or photo detection sites and individual identification of mountain lions from photos appears unreliable for the camera approach. Until these methods are further developed for mountain lions, track surveys and helicopter probability sampling mountain lion tracks appear most promising in estimating mountain lion populations for management application.

Track surveys have been used to monitor mountain lion populations in California (Smallwood 1994, Smallwood and Fitzhugh 1995) and Arizona (Cunningham et al. 1995). This method requires transect sampling areas where mountain lion tracks are detectable and provides presence-absence data with confidence interval estimates. Beier and Cunningham (1996) reported that sampling 140 and 110 8-km-long transects would be required to detect 30% and 50% population declines, respectively (80% power, $\alpha = 0.05$). The difficulty in implementing track surveys is ensuring transects are well distributed throughout the population in areas where access may be limited and the unpredictability of favorable tracking conditions. The level of

effort required to detect useful population changes likely limits application of this method to once every few to several years.

Becker (1991) and Becker et al. (1998) addressed helicopter probability sampling of snow tracks to estimate lynx and wolf population size in Alaska. This method requires sampling animal tracks during helicopter surveys and then following tracks from beginning to end to estimate the probability of detection for each track observed during surveys, and therefore requires consistent snow conditions for the duration of the survey. Helicopter probability sampling provides population and confidence interval estimates derived from the inverse of the detection probabilities for tracks in the sample. Van Sickle and Lindzey (1991) applied this method to a low-density Utah mountain lion population of known size and obtained an accurate but imprecise (high variance) population estimate. Anderson et al. (2003) investigated this method further using computer simulations of mountain lion GPS data (≤ 6 locations/night) to simulate mountain lion tracks and reported that mountain lion population changes of 15-30% could be detected (90% probability) for medium-high density mountain lion populations (23-35 independent mountain lions/1,000 km² or 386 mi²) depending on sampling effort (transects spaced 2 to 3 km apart). Both Becker (1991) and Anderson et al. (2003) noted the logistical difficulty and added expense of completely following tracks during surveys and suggested using telemetry data from radiocollared animals in the population or GPS movement data from similar habitat types during similar seasons to estimate track lengths. Anderson et al. (2003) noted that an area of about 2,000 km² (771 mi²) could be surveyed in 2 helicopter days for about \$8,000-\$10,000. Thus, helicopter probability sampling mountain lion populations would be limited to relatively small areas and likely only affordable to management agencies every few to several years.

ADAPTIVE MOUNTAIN LION MANAGEMENT APPROACH FOR WYOMING

Mountain Lion Hunting Season Structure, Hunting Methods, and Hunter Effort Indices: Since 1980, mountain lion harvest in Wyoming has been controlled using harvest quota management. Harvest quota management maximizes management flexibility by maintaining high hunting opportunity and controlling harvest by assigning total and sometimes female subquotas by hunt area depending on local management objectives. Rarely are harvest quotas exceeded in Wyoming, but heavily roaded areas are more prone to multiple hunters harvesting mountain lions at the end of the season thereby exceeding harvest quotas. If exceeding harvest quotas becomes a recurring problem, limited entry seasons could be established in those areas or quotas could be adjusted anticipating additional harvest similar to past seasons.

Mountain lion hunting seasons in Wyoming typically occur from September 1 through March 31 lasting 212 days. Year round seasons are established in 2 areas with high depredation incidents to provide opportunity for licensed hunters to take depredating mountain lions as a substitute for removal by agency personnel. Most mountain lion harvest (>90% annually) occurs during the winter months (November-March) when snow cover provides optimal tracking conditions. Although few mountain lions are harvested during September and October, this period provides hunting opportunity for hunters opportunistically during big game seasons or using predator calls.

Although some individuals and groups criticize the use of hounds for hunting mountain lions, this hunting method is an efficient management tool, which allows optimal dispersal of hunting pressure and minimizes harvest of adult females primarily due to vulnerability differences between hunting methods. Tracking mountain lions while hunting with hounds also increases the opportunity for hunters to detect and avoid family groups.

Currently, hunting information is only recorded from successful hunters when registering harvested mountain lions during the mandatory inspection process. Catch-per-unit-effort indices can be useful to monitor impacts to hunted populations assuming there is an identifiable relationship between hunter effort and the number of animals in the area hunted. Hunter effort data from only successful hunters has changed little the past 20 years has not proved useful in assessing mountain lion population trends (Appendix II, Fig. II-2). Additional information from unsuccessful hunters may prove more useful in evaluating these indices and knowledge about the number of unsuccessful and successful hunters hunting an area may explain changes in harvest level in cases where other information does not (i.e., due to changes in the number of hunters hunting an area). Regardless, data from unsuccessful hunters will enhance the management database and likely contribute to other harvest data currently collected.

Mountain Lion Habitat Management: Anderson et al. (in review) developed a winter mountain lion habitat model from GPS data collected in the Snowy Range, Wyoming, and validated model predictions using historic harvest locations 1996-2005 from the Bighorn, Sierra Madre, and Snowy Mountain Ranges. Habitat modeling efforts by Anderson et al. (in review) focused on the winter period (November-May) because this is the period when mountain lion activity is most limited due to deep snow at higher elevations resulting in ungulate concentrations on low elevation winter ranges, human development projects are vastly more common on low elevation winter ranges than on higher elevation summer ranges, and the vast majority of human-caused mountain lion mortality occurs during this period (>90% annually). The winter mountain lion habitat model is currently being used to delineate core winter mountain lion habitat statewide (Figs. 1 and 5). Thus far, most contiguous core mountain lion habitat in Wyoming has been delineated with the exception of the Southwest LMU, Northeast LMU, and hunt areas 14, 22, 25 and the Converse County portion of hunt area 6 (refer to Appendix III). Habitat maps for the other areas will be completed when detailed vegetation data layers are mapped and ground verified (e.g., Landsat Enhanced Thematic Mapper data at 30 m resolution); efforts are currently in place to complete vegetation data layers statewide.

Our intent for the mountain lion habitat model is to delineate suitable winter mountain lion habitat for resident adults (i.e., core mountain lion habitat) and exclude marginal habitats used as transition areas by transient subadults. Delineating core mountain lion habitat allows assessment of potential impacts from proposed development projects and application of mountain lion mortality densities to be used in development and assessment of management objectives (see next section below). Based on evaluations using historic harvest distribution (Fig. 4), the model appears to work well in most regions of Wyoming. Final acceptance of mountain lion habitat model predictions is pending regional review based on local knowledge of mountain lion habitat use during winter.

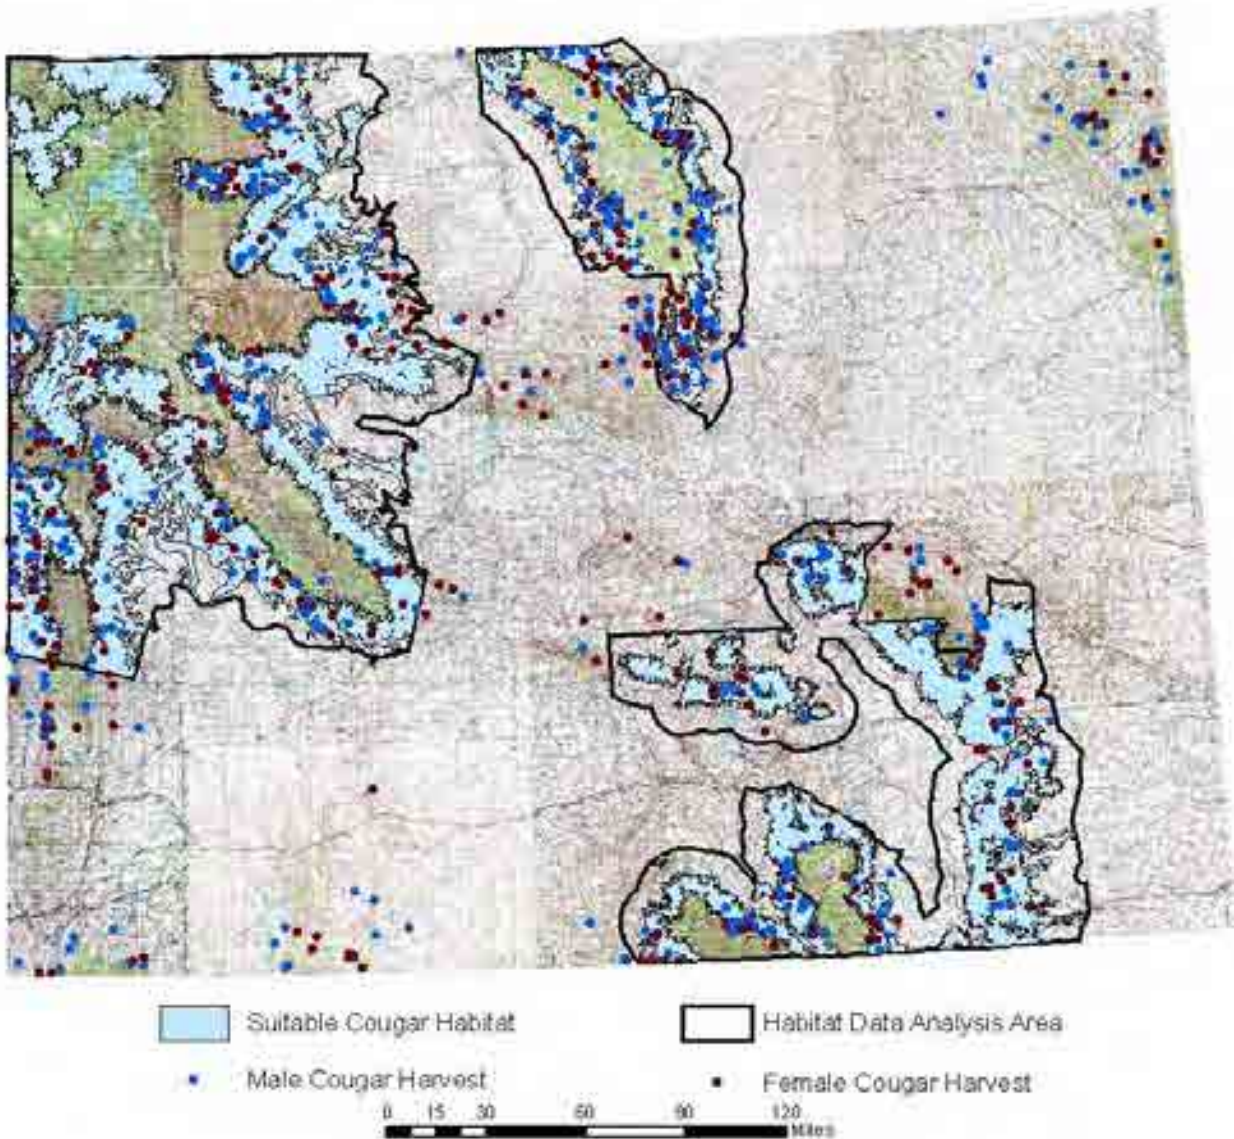

Figure 4. Winter mountain lion habitat model predictions relative to mountain lion harvest locations by sex, fall 2000-spring 2005. Winter mountain lion habitat represents core habitat of resident adult mountain lions and excludes marginal habitats occasionally used as transition areas by transient subadult mountain lions.

Habitat management efforts should include conserving large tracts of connected habitats that have the characteristics preferred by mountain lions and their prey. The Department's efforts to maintain high quality ungulate habitat should benefit mountain lion populations, and application of the mountain lion habitat model will provide opportunity to evaluate potential impacts from proposed development projects.

Management Criteria for Establishing Mountain Lion Management Objectives: The Cougar Management Guidelines Working Group (2005) suggested managing mountain lion populations

by managing source and sink subpopulations. As stated previously, the hunt area and management unit approach currently used in Wyoming lends itself well to this concept and has likely, by default, maintained source-sink mountain lion population dynamics since the early 1970s by maintaining relatively high lion densities in some portions of the state (i.e., source areas) which support recruitment of young lions into other areas managed at low population densities (i.e., sink areas); maintaining source mountain lion habitats allow persistence of mountain lions in other habitats experiencing high mortality rates. The CMGWG did not provide specific guidelines on how to delineate source and sink mountain lion habitats other than to establish large-unhunted refuge areas to offset population sinks that experience high human-caused mortality. However, refining this approach by applying sex-age composition of harvest and annuli age of harvested adult females addressed by Anderson and Lindzey (2005) and applying the Wyoming mountain lion habitat model (Anderson et al. in review) to evaluate density of human-caused mortality provides criteria to establish source and sink mountain lion management. Based on Anderson and Lindzey (2005) and evaluation of harvest densities presented here for mountain lion population decline (Figs. 2 and 3) and increase (Fig. 2), the following criteria appear appropriate for establishing source-stable-sink mountain lion management:

Hunt area management objectives:

1. Sink management: reduce mountain lion densities
 - a) Maintain density of human-caused mortality >8 mountain lions/1,000 km² (386 mi²).
 - b) Achieve adult female harvest $>25\%$ of total harvest for 2 of 3 seasons.
 - c) Progression in mean age of harvested adult females should decline to <5 years old.
2. Source management: maintain human-caused mortality levels that allow mountain lion population growth or maintenance of relatively high mountain lion densities.
 - a) Maintain density of human-caused mortality <5 mountain lions/1,000 km² (386 mi²)
 - b) Maintain adult female harvest $<20\%$ of total harvest.
 - c) Maintain older-age adult females in the population (>5 years old). This will be difficult to identify without additional sampling due to low sample size from harvest, but would be expected for lightly hunted populations.
3. Manage for stable mountain lion populations: maximize long-term hunting opportunity.
 - a) Maintain human-caused mortality density between 5-8 mountain lions/1,000 km² (386 mi²)
 - b) Adult female harvest should not exceed 20% of total harvest for more than 1 season.

- c) Maintain intermediate aged adult females (mean \cong 4-6 years old) in the harvest. Adequate age evaluation may require averaging age data over time to achieve meaningful sample sizes.

LMU management objectives:

- The LMU management objective should attempt to achieve the criteria above for source, stable, or sink mountain lion management at the LMU level. The objectives chosen by managers will be based on the adjacent management priorities, size of the LMU, maintaining recreational opportunity, maintaining source mountain lion populations, as well as depredations and other factors to achieve the overall management goal of sustaining mountain lion populations throughout core habitat at varying densities depending on management objectives.
- Coordinating management efforts with adjacent states would be most desirable for the smaller LMUs (i.e., Northeast and Southwest LMUs) where the majority of connected mountain lion habitat extends beyond Wyoming. Source or stable management could be maintained without interagency coordination, but sink management could also be implemented when sufficient source habitat has been identified in adjacent areas.

Acknowledging managers rarely, if ever, have precise information to measure success of management objectives, that mountain lion densities vary regionally, and the criteria proposed here are general guidelines, these guidelines should be compared to one another and applied adaptively to assess success of management prescriptions. For example, an area managed with the objective of stability and receiving a mountain lion removal density of 7 mountain lions/1,000 km² (386 mi²), but relative adult female harvest exceeds 25% and harvested adult female annuli ages have declined below 5 years old likely suggests mountain lion population decline rather than stability. Conversely, an area managed with the objective of sink and receiving harvest densities of 10 mountain lions/1,000 km² (386 mi²), but relative adult female harvest remains below 20% and older-age females (>5 years old) are consistently harvested suggests population stability (e.g., hunt area 23 in Table 4). Applying management objectives in an adaptive management framework, where density of human-caused mortality, harvest composition, and age of harvested adult females are monitored relative to expectations (criteria above) allows assessment of whether or not management objectives are being achieved and if management strategies should be modified to produce the desired outcome. Based on mountain lion management criteria averaged over the past 5 years for single or combined hunt areas of at least 1,000 km² of core mountain lion habitat (Table 4), 9 regions (1 to 3 hunt areas each) currently qualify as source areas, 7 as stable areas, and 1 as a sink area; 2 regions appear intermediate between source and stable and 2 regions intermediate between stable and sink (Fig. 5).

In implementing and evaluating mountain lion management objectives based on human-caused mortality density, proportion of total harvest comprised of adult females, and mean age of harvested adult females, it may be necessary to maintain consistent harvest objectives and combine data spatially or temporally to obtain meaningful information. Examples include hunt

Table 4. Annual 5-year average (fall 2001-spring 2006) of human-caused mountain lion mortality density (mountain lions/1,000 km²), proportion of adult females in the total harvest, adult female annuli age (*n* = sample size), management status (source, stable, or sink), and area of core winter mountain lion habitat for Wyoming mountain lion hunt areas^a and management units (LMU).

^aInsufficient vegetative data for hunt areas 1, 11-14, 16, 22, and 24-25 to calculate core mountain lion habitat and mortality density.

^bAnnuli age estimated from the number of rings evident after cross sectioning of the first premolar. Mean annuli ages from small sample sizes ($n < 5$) should be interpreted with caution.

^cStatus assigned based on the majority of the 3 criteria examined. Status criteria: source = mortality density <5 mountain lions/1,000 km², <20% of total harvest includes adult females, mean adult female annuli age >5 years old; stable = mortality density of 5-8 mountain lions/1,000 km², proportion of harvested adult females should not exceed 25% of total harvest for more than 1 year, mean annuli age of adult females should be intermediate to source and sink areas (e.g., 4-6 years old); sink = mortality density >8 mountain lions/1,000 km², >25% of total harvest includes adult females for 2 years, mean adult female annuli age declines to <5 years old.

^dHunt areas with <1,000 km² of core mountain lion habitat were combined with adjacent hunt areas within the same mountain range.

^eCriteria separated with “ / ” indicate intermediate management status. Management criteria separated with “to” indicate a transition in management status over the 5-year period based on trends in annual data.

^fAmount of core mountain lion habitat subject to change in hunt areas 5 and 6 following completion of improved habitat data layers and Regional review. Lack of vegetative data for hunt areas 16 and 25 precludes core habitat delineation and mortality density calculations for these hunt areas.

areas receiving low harvest levels or hunt areas of small geographic size. Small hunt areas can be combined with adjacent hunt areas and information from lightly hunted areas can be averaged over time to improve sample sizes (e.g., Table 4). Evaluating annual changes in management criteria are also important to determine if the population may be changing due to annual shifts in mortality density, harvest sex/age composition, and/or age of adult females, especially in areas experiencing moderate to high harvest levels; averaging management criteria over time may mask shifts in management status that are otherwise evident from annual changes in management criteria (e.g., hunt areas 7, 21, 22, 20, 2 & 29, and 26; Table 4). For example, mountain lion population reduction can be achieved in a short time period (>50% reduction; Logan and Sweanor 2001, Anderson and Lindzey 2005) in areas that are accessible to hunters where high harvest densities, increase in adult female harvest, and decline in age of adult females occurs within 2-3 years and subsequent management criteria suggest stability following the initial reduction (Fig. 3).

Figure 5. Current Wyoming mountain lion management status by hunt areas (numbered) within mountain lion management units (WE = west, NC = north central, NE = northeast, SE = southeast, SW = southwest). Status assigned based on the majority of the 3 criteria examined: source = human caused mortality density <5 mountain lions/1,000 km², $<20\%$ of total harvest includes adult females, mean adult female annuli age >5 years old; stable = human caused mortality density of 5-8 mountain lions/1,000 km², proportion of harvested adult females should not exceed 25% of total harvest for more than 1 year, mean annuli age of adult females should be intermediate to source and sink areas (e.g., 4-6 years old); sink = human caused mortality density >8 mountain lions/1,000 km², $>25\%$ of total harvest includes adult females for 2 years, mean adult female annuli age declines to <5 years old (Table 4). Unable to calculate mortality density for hunt areas 1, 12, 13, 14, 16, and 22 due to incomplete habitat data. White areas represent primarily open vegetative types and contain low-density mountain lion habitats.

Other factors to consider are the similarity in harvest composition for high and low-density populations and the duration for establishing source management areas. Anderson and Lindzey (2005) observed that harvest composition progressed from primarily subadults, to adult males, and finally to adult females with mountain lion population decline, but observed similar harvest composition to a high-density population, composed primarily of subadults, when the population was at low density. Harvest composition composed primarily of subadults may suggest a high density population where the less vulnerable adults have not yet been greatly exposed to harvest or conversely that the population is actually at low density where the majority of the adult segment of the population has previously been removed (via disease, past harvest levels, etc.) and most of the individuals in the population are immigrants from other populations. Approaches to determining whether high subadult harvest/low adult harvest suggests high or low mountain lion densities include comparing other harvest criteria, evaluating changes in harvest data over time (e.g., Table 4), and evaluating relative harvest of subadult females. Based on the current season setting structure in Wyoming where management objectives are established every 3 years, we suggest monitoring management criteria for the previous 2 management cycles (6 years) to adequately determine whether populations may be increasing, decreasing, or remaining stable. Low density of human-caused mortalities ($<5/1,000 \text{ km}^2$) for a 6-year period would indicate a high-density population, as would a majority of females in the subadult harvest suggesting numerous adult females producing young within the population. Ideally, source management areas should be maintained over time. If changes in social or biological conditions warrant shifting from source to sink management, 3 years should be sufficient to reduce mountain lion densities assuming sufficient access, but returning to source status will likely take longer. Numerical recovery can occur within 3 years (Logan and Sweanor 2001, Anderson and Lindzey 2005), but returning to the older age structure consistent with a functioning source population will benefit from source management for 2 management cycles (i.e., 6 years).

Another issue relative to source-stable-sink mountain lion management that should be addressed is the size at which an area may serve as a source subpopulation and the relative area and juxtaposition of source-sink mountain lion habitat necessary to sustain mountain lion populations at landscape levels. This issue has not been well addressed at this time, but work by Beier (1993) may offer some guidance. Beier (1993) suggested areas as small as $600\text{--}1,600 \text{ km}^2$ ($231\text{--}617 \text{ mi}^2$) would likely sustain viable mountain lion populations assuming 4 immigrants every 10 years, and higher levels of immigration would allow even smaller areas to support mountain lions. Genetic evidence suggests Wyoming mountain lion populations are well connected, with the estimated number of migrants per generation ranging from 6-30 among geographically distinct regions (i.e., LMUs; Anderson et al. 2004). Thus, areas of at least $1,000 \text{ km}^2$ (386 mi^2) would appear sufficient to serve as source areas in Wyoming. The amount and juxtaposition of source mountain lion habitat relative to sink habitat necessary to sustain mountain lion populations at landscape levels, however, is still unresolved. Past mountain lion management and recent management status (Table 4, Fig. 5) suggests the current amount of source mountain lion habitat has been sufficient to sustain mountain lion populations statewide. In addition, maintaining source or stable management objectives at the LMU level should support large-scale mountain lion population persistence and this approach may preclude the need to specifically delineate the ratio of source:sink mountain lion habitat relative to hunt area management objectives.

In addition to assessing mountain lion population trends for stable or sink management areas, periodic mountain lion population monitoring will also be useful to confirm the status of source populations. Harvest data may be sufficient to reasonably evaluate trends for areas managed as stable or sink populations, but likely insufficient to adequately evaluate status of source populations. Confirming the status of areas intended to support mountain lions at landscape scales will be a useful component in source-stable-sink management of mountain lion populations in Wyoming. Population estimation methods (e.g., track surveys, helicopter probability sampling, mark-recapture methods if they become applicable for estimating mountain lion populations) should be applied every 3-5 years (e.g., 1 hunt area/LMU) to confirm mountain lion densities are consistent with populations that are at or near carrying capacity. Ability to formally survey source areas, however, will be dependent on Department budget constraints. If budget constraints do not allow formal surveys of source areas, other approaches should be investigated to confirm the status of source populations (e.g., less intensive track surveys, hunter interviews, etc.).

Mountain lion management objectives should be based on local and regional biological and social considerations. Management objectives to reduce mountain lion densities should be proposed when the expected outcome will result in (1) reduced human conflicts (e.g., human-mountain lion encounters, mountain lion incidents near human development), (2) reduced depredation incidents, or (3) to alleviate predation pressures on ungulate populations that are below the ungulate population management objective primarily due to mountain lion predation rather than habitat conditions. Success of management actions should be monitored to determine if reducing mountain lion densities achieve the desired outcome by recording changes in human conflict levels, depredation incidents, or ungulate population parameters (e.g., changes in female:young ratios). In the case of predation impacts to ungulate populations, additional data collection may be necessary to determine if reducing mountain lion numbers has resulted in increased ungulate numbers, and will depend on the availability of additional funding to monitor the ungulate population response. Changing management strategies over time, while monitoring the effects will provide an adaptive management approach to evaluate the success of mountain lion management prescriptions.

In areas where human conflicts and depredation incidents are not an issue and ungulate populations do not appear to be strongly influenced by predation, stable or source management objectives should be implemented. Managing areas for stable mountain lion populations should maximize long-term hunting opportunity, and source population management should offset reduction in other areas managed as sink populations. In areas of Wyoming where hunter access is limited (National Parks, refuges, ungulate winter range closures, private lands), sink (e.g., hunt area 2) or even stable management at lower densities (e.g., hunt area 28) may not be possible. These areas have served and will continue to serve as source mountain lion populations as long as access remains limited.

NUISANCE MOUNTAIN LION MANAGEMENT

Livestock Depredations

Mountain lions will kill most species of domestic livestock, although sheep and cattle tend to dominate depredation records (Lindzey 1987). In Arizona, Shaw (1983) reported that 93% of mountain lion-killed cattle examined were calves (typically <300 lbs.), and although all age classes of sheep were killed, lambs were preferred. Cattle losses to mountain lions are rare in Wyoming (Fig. 6) primarily due to calves being born away from mountain lion habitat compared to other areas of the southwestern U.S. where calves are born in mountain lion habitat (e.g., the desert southwest; Shaw 1977, Cunningham et al. 1995). Mountain lion depredations of horses, llamas, goats, poultry, pigs, and other types of livestock have also been documented (Tully 1991). Data from Wyoming, 2000-2005, indicate approximately 97% of the damage claims submitted for reimbursement were for sheep, primarily lambs and ewes (Fig. 6; Wyoming Game & Fish Department 2005). Other livestock occasionally killed include horses, cattle, goats, and pigs. The loss of domestic pets near residential areas is also on the increase in urban areas, primarily due to human development into occupied mountain lion habitat (Davies 1991).

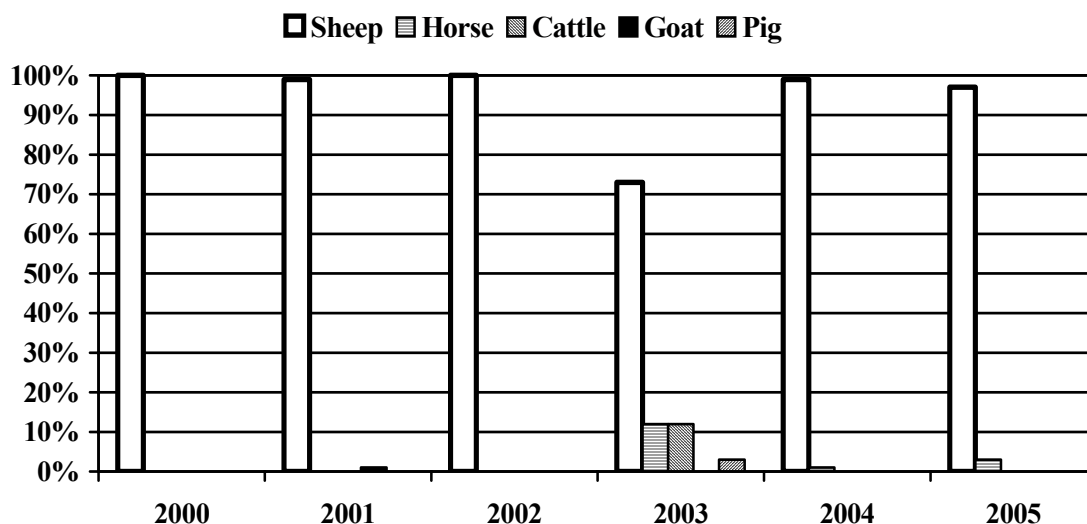

Figure 6. Percentage of mountain lion damage compensation in Wyoming by type, fiscal year 2000-2005.

Wyoming Statute §23-1-901 provides for monetary compensation of damage to livestock caused by mountain lions, and W.S. §§23-3-115 allows property owners or their employees and lessees to kill mountain lions damaging private property, given they immediately notify the nearest game warden of the incident. They may keep the pelt and skull if they purchase a Wyoming game tag. Because of this statute, Wyoming obtains annual information on the number of reported conflicts between mountain lions and domestic livestock and provides compensation for those losses. The number of damage claims submitted to the Department has varied between 1980 and 2005, ranging from under 5 to over 40 (Fig. 7). During that same time period, compensation paid to

livestock producers ranged from just over \$7,400 to just under \$110,000 (Fig. 8). Compensation does not correspond to the number of claims submitted in all years. For example, in fiscal year 2003, 21 damage claims were submitted for payment and only \$10,131 was paid to producers compared to 2005 when only 10 claims were submitted that resulted in \$39,000 in compensation. This is due primarily to the loss of expensive livestock, primarily horses, in some years.

Figure 7. Trend in the number of damage claims submitted for Wyoming mountain lion depredations, fiscal year 1980-2005.

Figure 8. Mountain lion damage claims versus payments to livestock producers in Wyoming, fiscal year 1980-2005.

Although Wyoming Statute allows for the take of mountain lions depredating livestock, mountain lions also have aesthetic value, trophy value, and removal costs that should be considered when making removal decisions (Lindzey 1987). In Wyoming, there are currently 2 approaches to reduce mountain lion damage including (1) remove the offending mountain lion and (2) increase take through sport hunting. Removal of individuals appears to be more accepted by the public than overall population reductions (Gasson and Moody 1995). Killing the offending mountain lion has been successful as a short-term solution, but livestock losses may eventually continue in the future where livestock remain in mountain lion habitat. Conversely, attempting to reduce mountain lion populations also does not appear to entirely resolve the depredation issue because it is usually very difficult to maintain a reduction program that is sufficient to reduce a population to the level required to reduce depredations. Public acceptance of such a program may or may not be maintained over a sustained period of time. We currently do not know the harvest level or length of time required to reduce lion populations to the point that livestock reductions would be reduced, but the adaptive management approach outlined in this plan will allow evaluation of this issue in the future. Therefore the Department will continue to consider all issues, including livestock depredation, to establish harvest quotas. Mountain lion populations have the ability to rebound from this level of reduction fairly quickly. Lindzey et al. (1992) documented that a population of mountain lions in Utah recovered from a reduction of approximately 42% in only 9 months. Similarly, mountain lion populations recovered from comparable reductions in New Mexico and Wyoming in 31 and 36 months, respectively (Logan and Sweanor 2001, Anderson and Lindzey 2005). Licensed hunters are occasionally directed to areas with damage in hopes of removing problem individuals, but agency personnel, either the Department of Agriculture's APHIS-Wildlife Services or the Wyoming Game & Fish Department, do most individual removals.

Management actions that target mountain lions that are a potential threat to human safety or cause livestock damage normally result in the lethal removal of the offending mountain lion. Current protocols provide agency personnel with a variety of options to address conflicts ranging from no action to relocation of the offending animal to lethal removal. Agency personnel respond and resolve incidents based on site-specific conditions. The Department will continue to document incident circumstances and outcomes.

Reducing non-harvest mortality should allow for increased hunter opportunity through season/quota regulations. Nevertheless, in most instances agency removal of specific individuals will be necessary to resolve specific depredation incidents. Striving for removal of only responsible individuals should help minimize losses, increase public acceptance, and maintain hunter opportunity.

Mountain Lion - Human Interactions

Interactions between humans and mountain lions have increased during the last 2 decades throughout most of the western United States and Canada (Beier 1991). Although mountain lion attacks are extremely rare, there were 9 fatal and at least 44 non-fatal attacks reported in North America between 1890 and 1990 (Beier 1991). The majority (66%) of the humans attacked were either unsupervised children or lone adults. Approximately 30% of the attacks occurred within sight of some type of developed area. Fitzhugh et. al. (2003) updated this information through

2003, and determined an additional 7 fatal and 38 non-fatal attacks had occurred since Beier (1991) published his data. The first recorded physical injury resulting from a human-mountain lion encounter in Wyoming occurred in 2006 near Laramie; fortunately, the injuries were minor. It appears younger-aged males, primarily yearlings, accounted for 42% of the attacks on humans (Beier 1991). Increased mountain lion numbers along with increased recreational use and urbanization of mountain lion habitat has created greater opportunity for mountain lion-human encounters. For example, new homes have been built on traditional mule deer winter range in Boulder County, Colorado, resulting in increased mountain lion sightings along with a dramatic increase in mountain lion predation on domestic pets (Sanders and Halfpenny 1991). Typically, when a mountain lion interacts with another animal, including a human, it determines whether the other animal is either prey or non-prey. If the animal is determined to be non-prey, it might become the target of aggressive behavior as the mountain lion may think the animal is a threat. Humans should attempt to maintain eye contact with an aggressive mountain lion and attempt to increase one's potential size by standing erect. It appears that attacks can be reduced if the mountain lion is aware that you are not a typical prey species. If an attack does occur, humans should fight back as aggressively as possible. Several attacks have been broken off due to this type of response (Fitzhugh et al. 2003). If humans have the ability to observe a mountain lion prior to an attack, they can interpret specific mountain lion behavior to assess the level of threat from the mountain lion (Appendix IV).

Not all mountain lion-human interactions can be avoided and, in some cases, humans do have the opportunity to modify their behavior to reduce the chance of an attack. It is much more effective for humans to modify their behavior than it is for people to modify mountain lion behavior. Guidelines that can reduce the chance of an attack are presented in Appendix V.

The Wyoming Game and Fish Department strives to minimize human conflicts with mountain lions while maintaining sustainable mountain lion populations for ecological, recreational, scientific, and aesthetic purposes. Coordination with county planning boards to minimize conflicts in suitable mountain lion habitats (Anderson et al. in review) should help reduce conflicts.

A "Protocol for Managing Aggressive Wildlife/Human Interactions", which includes mountain lions, was completed in 1999 (Moody et al. 1999). Major components of this protocol include procedures for reporting, documenting, and investigating incidents. This document is designed to aid Wyoming Game and Fish Department personnel in conducting investigations and assure appropriate coordination with other State and/or Federal agencies. Accurate reporting and periodic analysis of this information will improve our understanding of the factors that promote conflicts and how to better address them.

PUBLIC INFORMATION AND EDUCATION EFFORTS

As with all large predators, some aspects of mountain lion management are increasingly controversial. The public is much more cognizant of issues associated with mountain lion management compared to the early 1990s. The Department traditionally relied on public contacts, open houses, and public meetings held in conjunction with season setting meetings to gauge constituent attitudes and values about managed species. This process does not appear to

provide a forum that all interest groups are comfortable participating in. The Department will consider alternative methods to engage these segments of the public, such as increased involvement in establishing population management objectives.

The Wyoming Game & Fish Department completed an attitude survey of Wyoming residents to assess public values and attitudes that might influence mountain lion management (Gasson and Moody 1995). No attempt was made to calculate confidence intervals around the survey results. As a result, these data are qualitative indicators of public attitudes. The distribution of the sample by county roughly approximated the distribution of Wyoming's population. Approximately 67% of the respondents reported they hunted at some point in their lives, and over 54% presently engaged in some form of hunting. Less than 9% of the respondents hunted mountain lions, and 65% of mountain lion hunters used dogs to pursue mountain lions. Over 71% of the respondents felt that mountain lions were a benefit to Wyoming. Only 11% felt that mountain lions were not a benefit to the state. Approximately 50% agreed or strongly agreed that mountain lion hunting should continue, while 29% of respondents believed mountain lion hunting should be discontinued, and 57% felt hunting with dogs should be eliminated. However, only 51% of the people surveyed were aware mountain lion hunting was legal in Wyoming, suggesting the Wyoming public may be uninformed about the issues surrounding mountain lion management in the state. Sixty percent of the respondents indicated they would benefit from additional information and education about this species.

Based on the results of this survey it was apparent the Wyoming Game and Fish Department should expand its efforts to educate the public on mountain lion management and provide those interested with the information necessary to aid the Wyoming Game and Fish Commission/Department in future management strategies. The Wyoming Game and Fish Commission/Department recognize the importance of keeping the public informed.

To address these concerns, the Department provided additional information to the public about mountain lion biology, management, and how to avoid conflicts with lions beginning in 1996. One specific publication entitled "Living in Lion Country" was developed and distributed to WGFD Regional offices throughout the state. The Department has worked closely with The Center for Wildlife Information to integrate this material into existing programs that have traditionally focused on grizzly bears. Mountain lion information has been included in the Department's "Living in Lion and Bear Country" workshops that are presented every spring around the state. These workshops include information on grizzly bear, black bear, and mountain lion biology and how to reduce conflicts. An updated public attitude survey would be useful to assess the success of additional information and education efforts implemented since the previous survey in 1995.

Although a species management plan provides direction for the responsible agency, it also provides a concise, complete overview of important issues surrounding the species, which can easily be circulated to the public. Thus, wide circulation of this plan will help inform and educate the public about current mountain lion management topics. Issues can change, as well as attitudes, so periodically surveying public opinion will be necessary, along with education updates following completion of surveys. Collectively, adequate ongoing education and

information efforts coupled with periodic public surveys will help the Commission optimally manage mountain lions to address the public trust.

The Department will institute new programs. Additional information will be put on the Game and Fish web site to assist hunters in being able to differentiate sex of individuals. Additional and continued training of Department employees will be implemented to assure personnel who field check harvested lions are adequately trained to determine sex and age.

FUTURE RESEARCH AND MANAGEMENT NEEDS

The adaptive management approach outlined in this plan will provide opportunity to evaluate many of the management needs listed below, while other management needs will likely require additional research efforts. Addressing mountain lion management needs that require additional research efforts will be implemented when and if additional funding becomes available with respect to other management priorities for the Wyoming Game & Fish Department.

Short Term Needs:

- Develop or cooperate with other agencies in the development of vegetation data layers sufficient for application of the mountain lion habitat model in regions of the state where data are currently lacking.
- Further evaluation and refinement of population monitoring techniques.
 - Explore the potential for new approaches that are cost effective and logistically feasible for management application.
 - Evaluate track surveys and helicopter probability sampling for periodically monitoring mountain lion subpopulations the size of hunt areas.
 - Investigate the utility of DNA and camera based mark-recapture methods for estimating mountain lion populations. Explore reliability of different attractants for enticing mountain lions into hair collection or photo detection sites, and evaluate ability of photographic technology to differentiate individual mountain lions from digital photographs.
 - Include hunter effort data from unsuccessful hunters to that collected from successful hunters to better evaluate catch-per-unit-effort indices in evaluating mountain lion population trends.
- Test mountain lion habitat model predictions using independent data sets (e.g., GPS locations) as they become available.
- Monitor success of sink management objectives in reducing human conflicts and depredation incidents.
- Conduct placental analyses from harvested females to confirm accuracy of female age class determination.

Long-Term Needs:

- Identify juxtaposition and amount of source mountain lion habitat necessary to sustain mountain lion populations at landscape scales.

- Evaluate the level at which sink management successfully reduces human conflicts, depredation incidents, and predation impacts to prey populations.
- Develop and evaluate application of simulation models to examine vital rates relative to source-sink mountain lion management.
- Improve knowledge of mountain lion-prey relationships.
- Investigate population dynamics of multi predator-prey systems.
- Investigate potential influences of exploitation on mountain lion population dynamics.

APPENDIX I. History of mountain lion management regulations in Wyoming.

As in other western states, management in Wyoming became increasingly conservative during the mid 1970s through the early 1990s, primarily to control the number and sex of lions harvested. Emphasis was placed on controlling the take of females until sufficient information was available to warrant increased harvest. Harvest quotas have been increased since that time in an effort to limit population increase in specific portions of the state.

From territorial days to 1973, mountain lions received no legal protection. The earliest statutory reference to mountain lions was in 1882 when the Council and House of Representatives of the Territory of Wyoming enacted Chapter 108, Section 1. This legislation authorized county commissioners to encourage the destruction of wolves (*Canis lupus*), wild cats (i.e., bobcats; *Lynx rufus*), lynx (*Lynx canadensis*), bears (*Ursus* spp.), and mountain lions by offering bounty payments. Although property owners, employees, and lessees are still allowed to kill any mountain lion causing damage to private property, bounty payments are no longer authorized. In 1973, the mountain lion was reclassified from a predator to a trophy game animal. Since then, regulations governing the take of mountain lions have become more restrictive with the establishment of shorter seasons, total mortality quotas, and female sub-quotas.

CHRONOLOGICAL SUMMARY OF MOUNTAIN LION MANAGEMENT REGULATIONS IN WYOMING

- 1882 The Wyoming Territorial Legislature passed a law authorizing County Commissioners to encourage the destruction of wolves, bobcats, lynx, bears, and mountain lions. The County Fund paid \$2.50 for each mountain lion killed. This was the first law authorizing bounty payments for mountain lions.
- 1884 The bounty payment for mountain lions was raised to \$5.00.
- 1890 The bounty payment was raised to \$6.00. The Territorial Legislature passed a law prohibiting the killing of mountain lions outside of the Wyoming Territory. Violation of the law resulted in a penalty ranging from \$25.00 to \$50.00.
- 1907 Applications for bounty payments had to be accompanied by an affidavit stating that the person presenting the skin, in said county, and within Wyoming, killed the animal. The animal had to be taken after March 1st. Persons could take predators (mountain lions) within State Game Preserves with the permission of the State Game Warden.
- 1910-1911 It was unlawful to enter the forest reserves of Wyoming for the purpose of chasing or coursing predators with dogs, unless the dogs were licensed. The license was \$1.00 per dog, per calendar year. It was permissible to take mountain lions during closed big game seasons on State Game Preserves with a permit from the State Game Warden.
- 1913-1914 It was lawful to use dogs on predatory species and on State Game Preserves with permit from State Game Warden.

- 1915-1916 Game animals could not be used as bait for the purpose of trapping predatory animals within Wyoming.
- 1917-1972 No changes in mountain lion regulations.
- 1973 The mountain lion was reclassified from a predator to a trophy game animal.
- 1974 The first mountain lion hunting season established. The hunt area was considered the entire state. The season ran for the entire calendar year, with a bag limit of 1 mountain lion per season. A license and fee was required, and hunters had to present the pelt and skull to the nearest Wyoming Game and Fish District Office within 10 days of harvest. Hunting with dogs was allowed and females with kittens at side and kittens were protected from harvest. The owner, employees, or lessee of said property could take mountain lions damaging private property.
- 1978 Mountain lion season ran from September 1—December 31 and January 1—March 31.
- 1980 Wyoming was divided into 22 hunt areas and 5 LMUs. Mortality quotas (total mountain lions) by hunt area were established. The season ran from September 1 - March 31.
- 1983 Hunt area 15 was divided into hunt areas 15 and 23.
- 1985 Hunters must report mountain lion kills within 72 hours to nearest Wyoming Game and Fish District Office or game warden.
- 1993 The pelt and skull were required to be presented in an unfrozen condition to allow extraction of two premolar teeth for aging, and to allow examination of the pelt to determine sex. Female mortality quotas established in some hunt areas.
- 1994 Hunt area boundaries revised to more closely correspond with known distribution. A total of 27 hunt areas existed.
- 1999 Hunt area 26 was eliminated from the Southeast LMU. Hunt area 6 was expanded in its place. Regulations revised to allow for the take of 2 mountain lions per person per year in hunt areas 7 and 21 to assist the Snowy Range mountain lion study. Hunters must purchase an additional license (\$15 for resident and \$75 for non-resident). Hunt Area 25 added to the southeast LMU.
- 2000 Hunt area 17 split with hunt area 26 being created in the West LMU to separate the Wyoming Range from the Salt River Range in the Jackson Region. Hunt area 27 added to the areas where two mountain lions can be taken in a calendar year. Biological year for analysis of harvest information changed to September 1—August 31. Hunt area 28 created to address potential harvest and damage on fee title lands within the Wind River Reservation. Hunt area 7 was eliminated from those where 2 mountain lions can be harvested annually.

- 2001 Hunt area 21 eliminated from those where 2 mountain lions can be harvested annually.
- 2003 Hunt area 2 in the Jackson region split to address hunter pressure issues. Hunt area 29 established in the southern portion of hunt area 2. Quotas set for three-year cycle to address data assessment issues.

Appendix II. Wyoming mountain lion harvest and harvest quotas, hunter effort for successful mountain lion hunters, and nonharvest-human caused mountain lion mortalities.

Figure II-1. Wyoming mountain lion harvest mortalities by sex (1975-1995) and age class (subadult = SA, adult = Ad; 1996-2006) and annual harvest quotas (1980-2006). Harvest year represents September of the given year through March of the following year; quotas reported from 1980-1984 were based on calendar year (Jan.-Mar. and Sept.-Dec. of the year reported). No harvest quotas were in place 1975-1979 and for hunt areas 15 and 22 (i.e., the southern Bighorn Mtns.) from 1986-1989.

Figure II-2. Hunter effort (average days hunted per harvest) for hunters successfully harvesting a mountain lion, 1986-2006. Harvest year represents September of the given year through March of the following year. Harvest years exceeding 4 days per harvest were primarily due to a single hunter hunting for unusually long periods during the hunting season (e.g., a hunter reported hunting for 90 days in 1993).

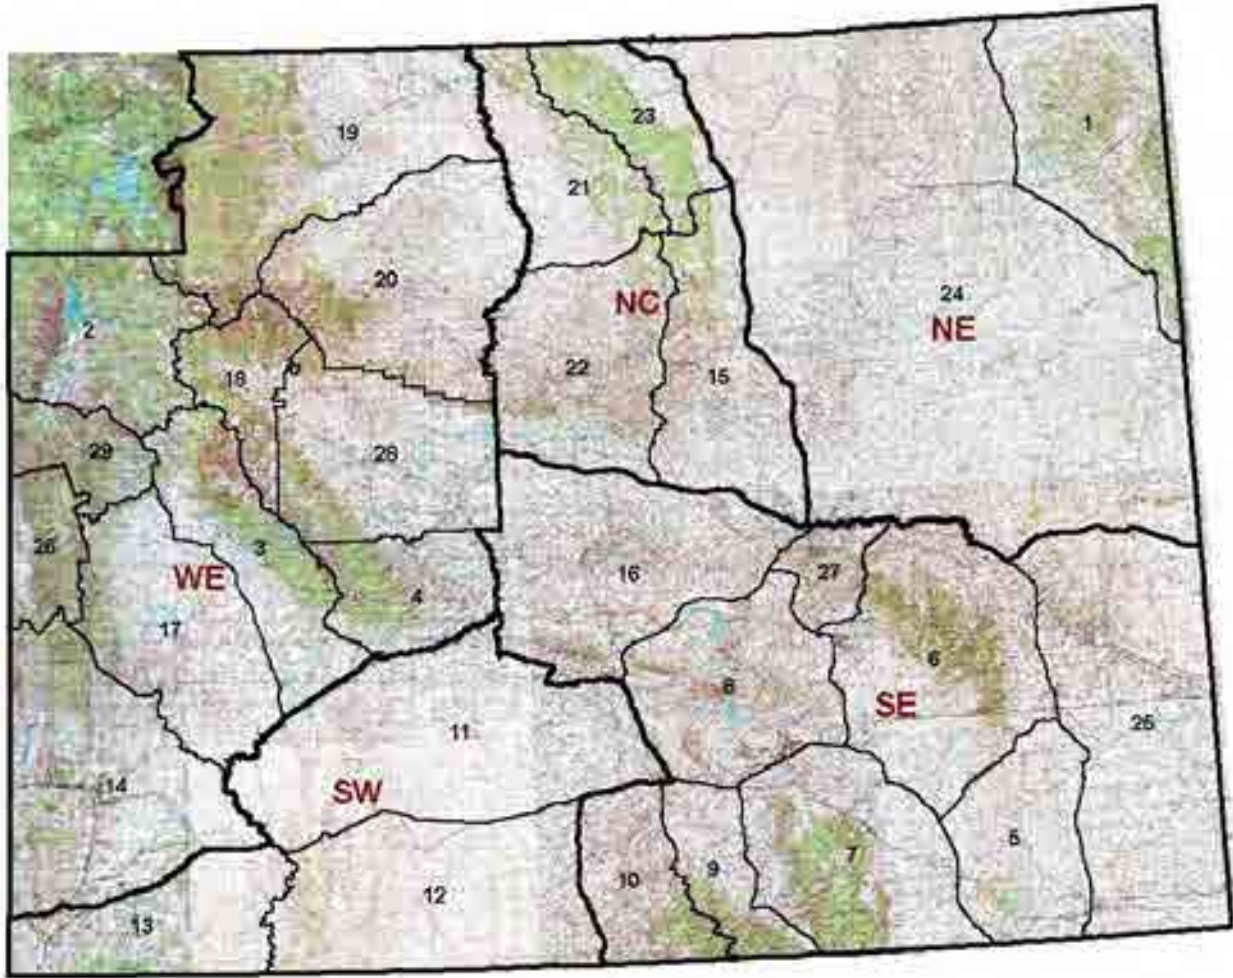

Figure II-3. Nonharvest, human caused mountain lion mortalities by cause reported in Wyoming, 1975-2006. Harvest year represents September of the given year through March of the following year. Other represents an electrocution in 1992 and a family group (1 female with 3 young) illegally poisoned in 2000. Nuisance mortalities include mountain lions depredating livestock or coming into close contact with human residence.

APPENDIX III. Wyoming mountain lion management units and hunt areas (numbered). Mountain lion management units: WE = West, SW = Southwest, SE = Southeast, NE = Northeast, and NC = North central.

APPENDIX IV. Wyoming mountain lion mortality form.

MOUNTAIN LION MORTALITY FORM

Hunt Area: _____ Region: _____

Date of kill: _____ TYPE: Legal _____ Illegal _____ Estrange Control _____ Other _____ Unknown _____
 If "Other" or "Unknown", probable cause of mortality: _____

PERSON WHO HARVESTED LION: Name: _____
 Address: _____ City: _____
 State: _____ Zip: _____ Phone: _____ Resident: _____ Nonresident: _____

METHODS/EFFORT: Days hunted: _____ Were dogs used? (Y/N) _____ If not, how was lion harvested? _____
 Was a guide/outline used? (Y/N) _____ Name: _____ Dog owner: _____
 Number of lions hunted: _____ Were you selective while hunting? (Y/N) _____ Number of lions trapped and released: _____
 Number of lions that were marked: _____ (Ear tag / tattoo / collar / other frequency) _____
 Number of fresh tracks not pursued: _____ (How many were single adults? _____ How many were adults with kittens? _____)

LOCATION/DRAINAGE: Where was lion harvested? _____
 Sec: _____ Township: _____ Range: _____ ITM Zone: _____ UTM Easting: _____ UTM Northing: _____

SEX AND AGE: Sex: _____ Est. Age: _____
 If female, presently lactating? (Y/N) _____
 Appear to have lactated in past? (Y/N) _____
 Canine ridges below gumline? (Y[2-3] / N) _____
 Any visible spotting on rear legs? (Y[2-3] / N) _____
 Visible bars on inside of front legs? (Y[2-3] / N) _____

REQUIRED SAMPLES

Number of teeth collected: 0 / 1 / 2 Pictures of teeth (Y/N) _____

Hair/skin sample (1/2" X 1/2") taken (Y/N) _____

sample paw print

Remarks: _____

Data record was WQF# _____ (Date Biological Services Called) _____

I, _____ of _____
 being duly sworn, depose and say that I am the holder of Wyoming Mountain Lion license # _____
 and lawfully took the above lion on _____ 20____ at Hunt Area # _____

Imperforated by _____ Date _____ Hunter's Signature _____

Any person who makes a false statement on the registration form regarding the date the mountain lion was taken or the hunt area in which it was taken shall be in violation of this regulation and, such violation shall be punishable as provided by Title 23, Wyoming Statutes for violation of Commission regulations.

Note: The person that checked the lion should forward the completed form and all teeth & hair samples to the Regional Office of registration and all Biological Services to update the harvest database. The Regional Office of registration will keep a copy of the completed form and send the original, along with the teeth and hair samples to the Trophy Game Section. Revised 04/04

Appendix V. Interpretation of mountain lion behaviors arranged in order of increasing risk to a human interacting with the mountain lion. Do not rely solely on these behaviors to assess risk, because mountain lions are ambush predators whose behavior usually is not observed before an attack on a human (from the Cougar Management Guidelines 2005, page 89).

Observation	Interpretation	Human Risk
Opportunistically viewed at distance	Secretive	Low
Flight, hiding	Avoidance	Low
Lack of attention, various movements not directed toward person	Indifference, or actively avoiding inducing aggression	Low
Various body positions, ears up, may be shifting positions, intent attention, following behavior.	Curiosity	Low-provided human response is appropriate
Intense staring, following and hiding behavior	Assessing success of attack	Moderate
Hissing, snarling, vocalization	Defensive behaviors, attack may be imminent	Moderate, depending on distance to animal
Crouching, tail twitching, intense staring, ears flattened like wings, body low to ground, head may be up	Pre-attack	High
Ears flat, fur out, tail twitching, body and head low to ground, rear legs “pumping”	Imminent attack	Very high and immediate

Appendix VI. Some measures, with supporting information, that humans can take during an encounter to prevent injury (from the Cougar Management Guidelines 2005, page 93).

Recommendations	Supporting Information
Keep children under close control, and in view. Pick up small children immediately if you Encounter a mountain lion. Do not hike alone.	60% of victims have been unsupervised children or lone adults.
Do not run.	Running and quick movements may Stimulate chasing and catching response.
Stand. Wave your arms. Raise jacket over your Head. Appear as large as possible. Move to higher ground if nearby. Throw sticks, rocks, or other objects if within reach and accessible without bending to low.	Prey size vulnerability, and “positioning” influences mountain lion response.
Avoid dead animals and never approach kittens. Talk calmly. Back away.	Non-prey may be attacked if viewed as a threat.
Maintain eye contact. Do not look away. But if mountain lion appears agitated use peripheral vision to keep track if its location.	Eye-to-eye contact often restrains large cats. Direct eye contact from prey may inhibit predatory action.
Be alert to your surroundings.	Cats exploit all vantage points/cover when investigating prey.
If attacked, fight back. Humans have successfully deterred attacks by becoming aggressive.	A cat grasps with its teeth only if it meets with no resistance. Violently struggling Prey may be released.
Secure pets and hobby animals in predator proof enclosures between dusk and dawn. Keep pets on leashes and off trails in the backcountry.	Domestic prey animals may sustain mountain lion populations at unnaturally high levels.
Keep garbage under control to avoid attracting raccoons, skunks, etc. Do not feed pets outside and remove extra feed from domestic animal pens. Do not feed wildlife.	Mountain lions may be attracted to concentrations of potential prey.
A mountain lion that treats humans as prey is a public safety threat.	Once a learned behavior develops it may not be possible to modify this behavior.
Mountain lions that enter yards or campsites to kill pets may be candidates for removal. Keep pets under control.	Once a learned behavior develops it may not be modifiable.

L

Dear New Mexico State Game Commission et al.,

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and we support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, we believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

We respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

We as hunters fully recognize the impacts of not adhering to science based management and fully dismiss views based solely on emotion.

Respectfully,
Ethan Shoop (New Mexico resident hunter)

This email is regarding the Bear and Cougar rule!

I have been hunting all my life and use it as a way to escape reality. Especially bear hunting. My uncle and I plan a trip every year to head out to bear camp and look forward to opening day all year long. We are actually heading up this weekend to get out and into the woods.

I ask that you leave predator management in the hands of the department of game and fish (NMDGF) As we support bear and cougar hunting here in New Mexico!

Good afternoon,

I wanted to voice my support of keeping the bear and lion hunting quotas in the hands of the biologists. I see a bunch of positives of hunting with hounds. The hunter can ensure they are not taking a female with young. It also teaches the bear/Lion to stay away from residence because of the barking. This leads to less depredation kills.

Thanks,

Jack Mulholland.

I support the hunting of cougar and bear with hounds to aid in the management of our predator population.

I have been involved with this for 50 plus years and our NMDGF have brought our numbers up to a healthy population with the current system.

Any changes would be detrimental.

Please support the hunting of bear and cougar rule update.

Michael,

Starting in the 1970s I was involved in hunter safety in NM for over 20 years. I've been involved in guiding (mostly Persian Ibex) for 39 years. Below is what I sent to the commission today.

Please, please support the continued hunting of bears and cougars in the upcoming four year cycle of hunting rules. The Game and Fish proposal is based on a great deal of research and historic data. Please be supportive of their recommendations.

Beyond that, on a nearly unrelated subject, I have personally found fresh evidence (typically by seeing tracks and blood in snow or mud) that show beyond any doubt that coyotes kill far more deer than the quantity they are commonly accused of killing.

Thank you for your consideration!

Dennis

I and my husband own a ranch and have a cattle allotment near Winston, NM. On the nearly 17,000 acres we have the largest population of bear compared to other ranches. I was told that it was "prime" bear habitat. Actually, it is prime cattle country and the bear happen to enjoy young calves they find laying in the canyons while their mothers feed. I have found way too many pieces and parts of what is left after the bear is done feeding. It is disheartening when you count on that calf growing to sale weight and providing a living for my husband and I and my daughter, her husband and their 2 year old child. The only way we can survive is to have a season when bear can be hunted. It would be even better if we could go back to a spring and fall bear season. There are more than enough bear to do that. Lion have also not only killed our calves but they kill mature bucks...not fawns, not does...mature bucks. We find dead heads all the time when we are searching for our cattle. What does this do to the deer herd? Well, one less buck to breed the does, no fawns and slowly the deer population diminishes and a huntable population will not be there for the public. A lion also hunted my husband when

he was out for a hike. Thank goodness he escaped harm. Without hunting you will be seeing the same results as California...lions WILL hunt humans and they will kill.

Our choice is for hunting both species. You don't manage predators...you don't try and selectively pick and choose. You control them thru hunting. Period.

Jennafer

Dear Commissioner,

I fully support the NMDGF on their management proposals for bear and cougar

hunting and their professional wildlife management.

Bear and Cougar numbers are at an all time high especially here in SW NM. The Game Dept. is doing a good job of managing these predators that take a huge toll on our elk calves and deer, and thereby keep our ungulate wildlife numbers healthy.

Thank you,

Tom Klumker

To Whom It May Concern:

I would like to take this opportunity to state that I STRONGLY support the hunting of bear and cougar. They are in fact a predator and I have personally seen where they have killed a full grown bull elk, cow elk, and grown deer. I was a rancher in the Little Hachet Mountains near Hachita, NM and I personally experienced mountain lion (cougar) kills of full grown desert big horn rans on more than one occasion. For these reasons, again, I am in support of hunting bear and cougar.

Respectfully,
Sid Savage

Subject: [EXTERNAL] Support of Bear and Cougar rule change

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Director,

My name is Bobby Duran. I am a lifetime resident of New Mexico. I have been a hunting guide in New Mexico since 2010 and a Wildlife and Fisheries Biologist since 2008. First, I would like to applaud the New Mexico Department of Game and Fish for their large predator management of bear and cougar in the state of NM. I am in full support of the actions Biologists and Managers have taken over the years concerning managing bear and cougar and think they are doing a fantastic job. I want to express my full support of the current proposed rule changes. Using sound science and modeling to adjust harvest quotas and manage each region according to each population within that unit is key to adaptive management of the species. I would urge each commissioner to allow the expert biologists and big game managers to make the best decisions possible for large predator management and that includes hunting. Hunting has been a great tool in keeping predator populations in check. We all know what happens when bears

become problems as rural and mountain towns continue to see a rise in problem bear encounters. I live in Angel Fire, NM and it has become a bad problem lately. No hunting or negative management actions would only make this issue worse and in the long run would result in detrimental impacts to bears by increased depredation kills by the Department. I urge each commissioner to not allow emotions and the mass outcry of the anti-hunting community to affect their decision when voting for the proposed rule changes for bear and cougar. Let science speak the truth and allow biologists to do their job and manage their species. I fully support hunting bear and cougar, including with dogs, and I fully support the proposed rule changes.

Thank you for your time in reading this.

Bobby Duran

Subject: [EXTERNAL] VOTE NO on Extending Current Hunting Limits on Mountain Lions!

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To Whom It May Concern:

Here's the main point: PLEASE, **DO NOT ACT TO EXTEND THE**

CURRENT HUNTING LIMITS ON MOUNTAIN LIONS (COUGARS).

The state of NM is quite complex. We tend to be lauded for our natural beauty and artistic community and jeered for our bottom of the list standing when it comes to public education, etc. We just finished up a successful 51st Balloon Fiesta which continues to make us a "bucket list state destination." We personally have met some of the best human beings on the planet in this very state.

Meanwhile, students at local public high schools continue to have ridiculous access to guns that wind up shooting their peers. Across the world, Israel and Palestine are going at it among other world conflicts like say, Ukraine... Global warming is contributing to wild weather swings resulting in loss of life and property. And, Covid19 still looms. There is plenty to cry over and lament.

Can we at least agree on NOT decimating slowly and surely the mountain lions of our state by **NOT granting the extension of current hunting limits on these majestic animals? Can we do something peaceful for once?**

Keeping the faith...

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To New Mexico Game & Fish Dept:

I am opposed to the proposal to increase the number of mountain lions to be hunted and killed. These lions face an increase in challenges within their environment. Climate change causing draught, flooding, and other events

threaten them and other wildlife. We should not be killing more of them!

Sincerely yours,

Lorraine Almo

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Greetings,

Will out of state hunters be included in the proposed rule?

I would pay hundreds of dollars for an out of state hunter license designation so that I may purchase an over the counter permit to hunt turkey, cougar, bear, etc. I only have the ability to apply for draw hunts, and even those are restricted to 6%.

Out of State hunters pay more for the privileges that residents enjoy. If you offered a hunting/fishing license instead of simply a limited permit we could have more opportunities to join in on family hunts with In State relatives and friends.

Many relatives and close friends are now seniors and ca. no longer hunt solo, they need younger hunters and hunting buddies (hunting groups) to safely hunt dangerous game.

Please keep us in mind.

Mountain lions are an important species for any ecosystem they are inhabitants in. They do not need to be hunted for any reason. The hunting of mountain lions is cruel and needs to be outlawed.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

Once again here's the email address to paste in your email:

Bear and Cougar hunting should be increased in some zones to help the elk and deer. Bears are hurting the calf crop in elk in the 16A,16B,16C,16D and 16E areas. Cougar are over running the 23 area and hurting the deer herds can't reproduce fast enough. The anti hunters have no idea what they are talking about. The coyotes have doubled in population expands with the loss of trapping and contest help keep their numbers in check. Thank you John S. Alexander email plt305576@gmail.com

Dear Game and Fish,

I support the current regulations regarding bear and cougar hunting. In fact I believe that cougar hunting could be increased. I have a cabin near Cimarron, and when I was a boy we would see large herds of mule deer throughout the Canyon. There are very few mule deer left in the area, and the ones that are there are much more cautious and alert. In the past few years a neighbor watched a cougar come out from under his deck and kill and eat his dog. Last year another neighbor watched two yearly cougars kill a fawn and eat it right in front of his cabin! I hike all the time in the Colin Neblitt and Barker WMA's, and every year I find several elk and mule deer fawn killed by cougars.

The harvest limits now set for cougars are to conservative, I believe they should be increased. The limits for bears seem to be adequate.

Please add my comments to the public comment you are soliciting as you set new rules for hunting these predators.

Cody B. Walker
NM native and lifelong sportsman

We need to run hounds to manage the population of lions and bears here in New Mexico without hounds lions are almost impossible to hunt, and if they are not hunted, the population will get out of control and they will wipe out the deer and elk population in the state. This is also a livelihood and a way of life for a lot of people. keep lion and bear hunting with hounds in New Mexico.

I am a new big game houndsman as of 2021 when I adopted a English walker pup not really knowing what the sport was all about. I grew up just knowing bird dogs as the only working class of dogs and had this very uninformed view of how dogs are used for hunting big game. Now having done research and getting into the sport it is clear that hunting bear with mans best friend (yes mans best friend since the dawn man helping and working together to provide food for the "pack.") That even entertaining a ban predator hunting would be not only devastating for agriculture communities (And the Metro area already having to trap and tranquilizer these large predators coming to the Intercity.) But also it would be a complete tragedy for the hunter making a living or like me making a way of life for me and may hounds. Ending hunting for our k9 friends will be ending them all together. The departments proposed increase in harvest limits is good idea and will directly affect the deer and elk populations for the better and other commenters on this need to learn something about carrying capacity. A topic the department teaches in hunter Ed.

I know that hunts are well thought out by professionals who track animal populations and herds, especially noting with drought issues and now rains, what is best for that population. I am not a hunter, but many college of my students were or were from families who hunted or supported hunting.

Anti-hunting groups do not acknowledge the professionalism of Game and Fish, outfitters who feed and house their children based on this income, ranches and a way of life kept alive by income from hunting. These anti-hunting groups, in a naive "save the little animals" perspective don't see how many young animals, deer, antelope, elk, calves, and others are destroyed by animals if not kept in check by hunting.

Please trust the trained professionals who are true do-gooders driven by research and knowledge, rather than well-meaning but ill-informed do-gooders who inadvertently cause damage to our wildlife population.

Thank you.

Greetings,

I come from a long line of hunting and fishing heritage. My father used to hunt and trap to help out food on the table for us kids. He would sell pelts as often as he could and when hunting season would come around everyone of us boys would purchase a deer license.

We would fill our freezer with game meat because we didn't have a lot of money to buy meat. We are slowly losing our rights as honest hunters to these Animal Activists and there has to be a Happy Medium between Humans and Wildlife.

The Coyotes and other Varmints are already wreaking havoc on livestock and young deer as well as Quail.

We need to stand up and defend our rights to do the activities we do much love doing for sport as well as for survival. I support the fight against the Lion and Bear bans.

Thank you, Reymundo.

We have finally reduced the cougar levels a little so we are seeing more mule deer and antelope it would be sad if we reduce the hunts on them now and lose the ground we have just gained thanks Pat Baca

Bear and Cougar hunting has been managed through New Mexico Game and Fish very thoroughly through by posting updated harvest results by unit which allows for excellent game population management in New Mexico, which keeps the population of these species at a level that are healthy and not a nuisance in populated areas. I wonder how these anti-hunting people would feel if cougar and bear populations were left out of control and they had their dog eaten by a cougar or their family member attacked by a bear??

Hi I know there is a lot of anti dog hunters trying to ban hounds hunting. I would like to show my full support of bear and cougar hunting or any kind of dog hunting. New Mexico needs to keep its traditions alive this is what we do, we hunt. Please do not take this away from us. This is all my family knows is running dogs, this is our life, this is what gets us up in the morning. So please protect our rights to hunt.

Sincerely, Colter Muldoon

My name is Garrett, Kirby and I 110% agree with the legal harvesting of bears and mountain lions with the use of hound dogs

It has been a way of harvesting animals for hundreds of years. Making hound dogs illegal for hunting use would increase the death rate in deer and elk populations and not forget even farmers livestock the predators in New Mexico still need to be regulated and the most efficient and humane way to regulate them is with hound dogs.

You are barking up the wrong tree. Pardon the pun. I have no support for predator hunting. Deer, elk, moose, buffalo/bison and other edible prey species are what should be hunted & not just for their headgear. We've moved too far away from spending effort to prove what great hunter's we are & instead we spend money. I remember when it wasn't a big rack that we went after but a big deer. Antlers won't feed anyone, yes I know that they can be sold to people in China for medicine, but really?

Anyway, I would never go into an environment & take out the controls, by that I mean the top predators. It would be irresponsible & ignorant of me. Soon New Mexico will be like Colorado, a bunch of folks who have lost the ability to live with predators and are terrified of coyotes, every wild animal is rabid & the wolves are coming, the wolves are coming, the wolves are coming!

Subject: [EXTERNAL] 2023 proposed bear rule
Date: Tuesday, May 30, 2023 4:56:24 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I would like to comment on the current proposal for the bear rule as summarized on the NMGF website.

I am adamantly opposed to changing the opening date of the bear season in BMZ 12 (GMU 34) to August 16th or any time in the month of August. I have hunted bears in this zone/unit since the late 1970s. The bear population today is a fraction of what it was 30-40 years ago. The late summer time frame is a critical time for the bear population here to put on the necessary weight for successful hibernation. The massive road system in this zone (both legal and illegal) makes it virtually impossible for a bear to travel anywhere without being vulnerable to harvest particularly with the use of dogs. As a full time resident of the zone/unit and property owner with property bordering National Forest lands including riparian habitats the sightings and sign from bear activity are noticeably absent even though our property is within the "suitable habitat" used to estimate bear populations here. In the last 5 years I have observed only 1 bear and even with multiple game cameras operated 365 days a year have only recorded 1 bear. Forty years ago it was common to see several bears a week simply driving forest roads in this unit. I maintained up to 18 bear hounds and hunted both during the fall and then spring seasons. Huge expanses of country with healthy bear populations then are literally devoid of bears today. The 2014 study used to estimate bear populations here has some obvious weaknesses in its' population estimates and is now almost a decade old. The Department has also given no consideration to the cumulative impacts of its hunting seasons on the rural community and residents here. Recent expansions of turkey, (resulting in the turkey season from hell this spring) elk, and barbary sheep seasons in this unit have had and will have negative impacts to the local community. There is no biological justification for adding additional days to the bear season. This unit is heavily hunted by not only resident hunters but is significantly hunted by non-residents during the bear and other seasons. It is time to put the welfare of the resource first rather than the recreational wants of a small segment of the public.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I would like to comment on the proposed changes to the cougar rule as currently summarized on the NMGF website.

The current one size fits all blanket statewide management strategy needs to be completely revised to meet regional differences in integrated management objectives and effectiveness of harvest techniques.

There is currently no need to maintain a statewide year round hunt season on public lands. The year round season originally applied only to private lands in order to try to attempt to minimize depredation interventions by NMGF personnel as licensed hunters could remove offending animals. The only zones where year round hunting on both public and private lands should be allowed are those with ungulate management issues related to cougar depredations or chronic livestock depredation issues. This would serve to focus hunting activities by licensed hunters in areas where they could potentially serve as management tools to achieve related harvest objectives and potentially minimize depredation complaints. I would recommend a September 1-March 31 general season in most zones to allow overlap with other primary hunting seasons to allow opportunistic harvest by licensed hunters in the field pursuing other species. A more liberal quota should also be applied in those zones with chronic big game ungulate or livestock depredation issues.

The harvest by licensed trappers on private lands also needs to be allowed under previous guidelines in those zones where the Department is currently paying contractors to remove cougars including by trapping. It makes no sense for license funds to be used to contract for removal of cougars while denying license holders the opportunity to engage in harvest. Over the last 2 decades the NMGF has very likely spent approximately 2 million dollars to remove 100s of lions from desert bighorn sheep areas alone. It defies all common sense to pay for removal of cougars that could be accomplished by license buyers at no cost to the Department.

Subject: [EXTERNAL] A Call to Defend Hound Hunting Traditions
Date: Sunday, August 20, 2023 10:22:11 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Commissioners,

Predator management has been a core of wildlife management since the beginning. Managing predators allows for both healthy predator populations and individuals. Removal of predator management systems could cause an overpopulation of predators which could lead to lions or bears searching for food in urban areas. This could lead to more human wildlife conflict which may in turn be taken care of by contracted hunters. Similar to other systems seen for whitetail deer and cougars in other states, removal of hunting opportunities that fund wildlife conservation could be replaced with contract hunters who cost tax payers money. Additionally, the use of hounds for hunting bears and lions allows for selective harvest of certain individuals to keep the populations at adequate sex ratios. The tradition of hound hunting is a long-standing practice in New Mexico and is very effective in managing predator populations. Please keep wildlife management in the hands of hunters that fund wildlife conservation rather than making the public pay for contract hunters and trappers to do the same job. Thank you for your time. I appreciate the ability to have feed back.

Dear Commissioners,

The lessons from the trapping ban debacle must not be forgotten. Unity is essential to stand against the relentless drive of some anti-hunting groups. Seeking middle ground often results in a slippery slope of continuous concessions. Let's remain firm in our evidence-based approach.

Continue the bear and cougar hunts!

Sincerely,
TALON POWERS

Dear Commissioners,

Protect cougar/bear hunting. In a rapidly changing world, New Mexico has a golden opportunity to refine hunting practices, emphasizing responsibility and sustainability. Considerations such as mandating the retrieval of edible game portions can not only elevate the state's hunting ethos but also address concerns raised by various sections of the populace. Adapting while preserving New Mexico's valued hunting traditions is the way forward.

Sincerely,
Jacob Franklin

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Commissioners,

I support the NMDG&F bear and cougar rule change proposal. The game commission should take some important steps to protect our state's hunting heritage from criticism from non-hunters. During the last legislative session a bill failed to pass that would have required hunters to remove the edible portions of bear, cougar and javelina from the field. Enacting such a requirement would do much to head off anti-hunting sentiment.

The game commission needs to do what it can to enact and support prohibitions on the waste of game including bear and cougar and other game species. Hunting bears and cougars is a longstanding tradition for many New Mexicans and people who travel to New Mexico from across the country. In addition to providing conservation funding, economic benefits from outdoor recreation, being a critical population management tool and bringing families together in the outdoors, the harvest of a bear or cougar provides countless nutritional meals for the lucky hunter and all those he/she shares the bounty with.

Sincerely,
Darrell Chalupa

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

****ATTN: NM Dept. of Game and Fish - PUBLIC COMMENTS for 8/25/23 Meeting (also, by PDF letter attached)**

Dear Friends and Respected Colleagues at NM Game and Fish,

As a 40+ year resident of NM living on +45acs of lands along SFNF, precious watershed and wilderness areas, I ask that you please enter into the public record and respectfully consider my comments below (and attached) re. the hunting of bears and cougars important agenda item scheduled at your upcoming meeting on 8/25/23 in Raton.

With greatest respect for the balancing of wildlife, ecosystems, outdoors, recreation and hunting interests during times of increasing climate, drought, catastrophic wildfire(s), and challenged forest (i.e., species) conditions, I request that you please pause, utmost consider and take into account the following key issues in your deliberations for making final recommendations, practice and policy decisions:

1. Given the uncertainty of habitat and population estimates of both bears and cougars, the quotas for both should be reduced, not raised. As given current climate, forest and catastrophic wildfire conditions there is increasing evidence to be made that 'kill quotas' for both species have been unjustifiably high in recent years.
2. Bears and cougars are now scientifically known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.
3. Killing bears and cougars for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.

3. Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected.

Current proposals to raise the kill quotas don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying.

4. The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is lacking and the public currently has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years.

There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.

Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.

Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal

treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophies' and recreation.

As such, we respectfully request NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

Thank-you for your consideration today and for your ongoing deliberations about these most vital issues for the proper respect and management of New Mexico's precious wildlife and lands into the future. Please feel free to contact me if there is any further information or discussion you would like to have re. my comments expressed herein.

Yours Respectfully,

Jai Lakshman

From: [Mickey v. Brussel](#)
To: [DGF-Bear-Cougar-Rules](#)
Subject: [EXTERNAL] About the hunting of bears and cougars for the next four years in NM
Date: Sunday, July 16, 2023 4:47:01 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Sir:

I want to convey my comments to you.

The current draft of the proposed rule recommends raising the kill quotas for bears, extending the bear hunting season, and “adjusting” kill quotas for cougars. But Game and Fish has NOT provided sufficient or coherent information about bear or cougar populations that allows the public or even wildlife biologists to judge whether their recommendations are sound!

---This lack of correct estimates means that quotas for both should be reduced, not raised, the kill quotas for cougars and bears have been unjustifiably high for too many years already!

We now know that both species are very important in regulating our ecosystems.

And both species can self-regulate their own numbers. Killing bears and cougars randomly, for "recreation and trophies" does not help address conflicts with people, in the contrary, it might cause more conflicts as trophy hunters typically go for larger, established individuals for their kills, disrupting important bear and cougar social structures.

Current proposals to raise the kill quotas are reckless, they do not use the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.

The hunting proposals lack scientific evidence. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. The people of New Mexico, most of them against killing cougars and bears, deserve honest numbers when it comes to wildlife "management", and these numbers are absent in the hunting rules now proposed for bears and cougars.

Besides, there is no indication that NM Game and Fish has accounted for the growing drought problems and the consequences of that for wildlife. Another reason to lower the kill quotas. Even segments of the hunting community find the practice of using dogs to chase cougars up the trees to be killed contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for trophies and "recreation". So I take this opportunity as well to ask NM Game and Fish to consider broad public opinion and at least adopt hunting rules that ban the use of dogs during cougar and bear hunting.

Sincerely:

Dept. of Game and Fish, Your department was had bad direction in the recent past that I disagree with: the killing of Feral Cattle in the Gila Wilderness by shooting them from helicopters and leaving their carcass to rot in the National Forest! There were much better (humane) proposals put forth that were turned down by you (Game and Fish) to get rid of these cattle, but you decided to not heed the communities and the Cattle Ranchers, etc.. It sure turned alot of people off. Now you're proposing to kill many additional wild, big game large animals that my family is against. Its a mismanaged directive. It is another example of the Gov't making poor decisions as were made with the "controlled burns" by the Nat'l Forest that led to the 345,000+ acer destruction of the Calf Canyon/ Hermits peak fires, the largest fire in N.M. ever posted. Then, the rains and floods came with more destruction. Those poor people in Las Vegas and Mora County are still suffering, and it will affect generations to come. These decisions have lasting effect. I voice my opinion again the killing of additional large game wildlife as a long time resident in New Mexico. This is just another Gov't agency making a poor decision that needs to be reconsidered!

Thanks, MaryJane Beisel Cook, 505- 237-0959.

Dear Commissioners,

Rooted in both tradition and research, New Mexico's wildlife management strategies, such as the bear and cougar rule modifications, underscore its dedication to conservation. This holistic approach ensures that the beauty and diversity of New Mexico's wildlife landscape are preserved for future generations. Let the hunts stay!

I am a non-resident of New Mexico who has traveled to New Mexico many times to participate in the excellent hunting there. I always appreciate the opportunity to add a cougar tag to my other species tags so that I might take an incidental cougar (when in season). This brings extra dollars into new Mexico for support of wildlife management. Please do NOT allow anti-hunting activists to dictate New Mexico hunting regulations.

Sincerely,

Sincerely,
John Frost

From: [Robert Kroger](#)
To: [DGF-Bear-Cougar-Rules](#)
Subject: [EXTERNAL] Adherence to New Mexico's Statutory Directives
Date: Sunday, August 20, 2023 7:01:10 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Commissioners,

Dear Commision,

I support the NMDG&F bear and cougar rule change proposal. The game commission should take some important steps to protect New Mexico's state's hunting heritage from criticism from non-hunters. During the last legislative session a bill failed to pass that would have required hunters to remove the edible portions of bear, cougar and javelina from the field. Enacting such a requirement would do much to head off anti-hunting sentiment.

The game commission needs to do what it can to enact and support prohibitions on the waste of game including bear and cougar and other game species. Hunting bears and cougars is a longstanding tradition for many New Mexicans and people who travel to New Mexico from across the country. In addition to providing conservation funding, economic benefits from outdoor recreation, being a critical population management tool and bringing families together in the outdoors, the harvest of a bear or cougar provides countless nutritional meals for the lucky hunter and all those he/she shares the bounty with.

Appreciate the opportunity to share my thoughts.

Sincerely,
Robert Kroger

Dear Commissioners,

Globally, the merits of hunting have been recognized not just as a tradition, but also as a significant conservation tool. The potential impact of discontinuing long-held practices like the use of hounds in New Mexico's bear and cougar hunting cannot be underestimated. The science should always guide these decisions, rather than shifting public opinion. Protect the hunts!

Sincerely,
Joe Chandler

From: [Paul Miles](#)
To: [DGF-Bear-Cougar-Rules](#)
Subject: [EXTERNAL] Advocacy for a Thoughtful, Science-Based Approach
Date: Sunday, August 20, 2023 7:43:11 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Commissioners,

Around the globe, hunting has always been a key player in wildlife conservation. The funds accrued, the management of animal populations, and the monitoring of habitats have yielded positive results. It's imperative to understand that discontinuing practices such as the use of hounds for bear and cougar hunting in New Mexico might have ripple effects. Such decisions, if made, should be backed by scientific data and not merely popular sentiment. Keep the hunts!

Sincerely,
Paul Miles

From: [Chip Martin](#)

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear Commissioners,

It's undeniable that hunting plays a significant role in wildlife conservation. From the funds generated through licenses to the active role hunters play in managing and monitoring animal populations, their involvement is essential. Abolishing the use of hounds and general bear and cougar hunting, based on non-scientific arguments, can result in unintended and detrimental consequences to ecosystems.

Sincerely,
Chip Martin

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hello,

I was surprised at the new proposal to allow killing of additional bears and cougars. This is a reckless and destructive proposal lacking scientific rigor and ethical competence. The game department's continuing focus on expanding the recreational killing of our wildlife is another clear example of why state wildlife management must be reformed and modernized.

Bears and cougars are both native to New Mexico and belong on this landscape in ecologically significant numbers. These species manage their own populations based on the availability of food and habitat. There is no credible evidence that either species needs to be lethally "managed."

Please reconsider for the future health of our unique environment.

Thank you,

Teresa Manlowe

Hello,

I think we need to let the biologists with fish and game manage the hunting and conservation of all game animals.

We do not need anti-hunters telling the game commission how to manage our wildlife. If that happens, we will eventually be overrun with animals that are inbreeding and are destined to diseases and have all kinds of deformities. This is an injustice not only for the bear and cougars, but all wild game.

Respectful,

George Mason

Dear Commissioners,

Wildlife management is not a popularity contest. The charge to manage our game populations to provide public recreation and food supply is essential to the commission's responsibilities.

Hunters have supported game management in our state for generations. The license fees and excise taxes they've willingly paid over the decades are responsible for the flourishing game populations that anti-hunters now would seek to protect from the very hunters who have nurtured them.

Sincerely,
Jon Giles

Dear New Mexico Department of Game & Fish,

I oppose the New Mexico Department of Game & Fish's proposal to kill more black bears and cougars through:

- 1) Making unspecified increases to hunting quotas.
- 2) Lengthening hunting season for bears in some areas.
- 3) Allowing elk and deer hunters to opportunistically shoot bears and cougars.

Your department has only a hazy notion of how many bears and cougars live in the state, since you estimate their population by extrapolating from limited study areas to much broader regions.

Despite these questionable numbers, your department's proposal gives no consideration to the effects the climate emergency may have on bear food sources and habitat. The climate emergency has been wreaking havoc on the habitat of bears, but this proposal doesn't acknowledge the persistent droughts that New Mexico has experienced over the last two decades. A study in Nature Climate Change revealed that the Southwest is the driest it has been since 800 B.C., making the bears' food and water sources increasingly hard to find.

The proposal also doesn't acknowledge the impact ongoing developments may have on habitat connectivity or how the use of hounds in hunting puts nontarget animals in danger and risks human safety.

Instead of killing more bears and cougars, the department should reject the bear and cougar rule and err on the side of caution by:

- 1) Reducing the hunting quotas of these two ecologically beneficial carnivores.
- 2) Refraining from increasing the lengths of their hunting seasons.
- 3) Prohibiting the use of hounds in bear and cougar hunting.

Thank you.

Sincerely,
Capt. Craig McClure

To whom it may concern.

I am an Outfitter and hunter in the state of NM. I live in Ruidoso, I hunt and guide here every year and strongly believe that we should open bear hunting in units 34 and 36 on Aug. 16th. I believe that the pressure it has put on units 37,38 during the August hunt from them being closed is not worth it. I do not think that units 34,36 being open for bear in August will harm any other hunts and it will give hunters the opportunity to spread out more in Southern NM. Even if we just open it for spot and stock hunting without the use of dogs.

Thank you for your time.

Date: Friday, August 18, 2023 1:08:04 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

This email is in reference to resetting the season start dates in GMU 34 and 36 to August to coincide with GMU 37. This would spread sport hunters out instead of having the majority of hunters in one unit between hound hunting and spot and stalk hunters.

Also I would like the commission to consider a spring season, the reason for this I believe would be to reduce summer encounters in urban areas.

Thank you for your consideration.

Chad Casson

Hello,

My husband and I own outfitting business in southern NM and just learned about the state opting to cancel the August bear season. This affects our business negatively and we would like to voice our opinion about it in attempt to reinstate the season. Please take into consideration that local business owners income and livelihood is affected by these new changes and the economy of NM will be negatively impacted. Most of our hunters come from out of state and support our economy. The bear seasons have quotas set to protect bear populations and this system has worked well for many years.

Thank you for your time,
Shelly Troyer

To whom it may concern,

I am FOR reinstating the August bear season. As a bear hunter, houndsmen, and NM registered guide I would like to see our season reinstated for August bear season. I am against shortening our season, period. As a bear hunter who spends close to 300 days a year in the bear woods, the population is very healthy!

Thank you

Hi I'm a former resident of New Mexico and have recently learned that the august bear season is in danger of being closed!

I am asking that it be reinstated for many reasons but the main one is population and health reasons for the bears! If hunting isn't allowed any longer they will become nuisances and ill because of over population of said animals and the food sources they enjoy will be scarce! This would cause endangerment to humans and livestock! So please do NOT allow them to angel bear hunting or predatory control in this beautiful state!

Sincerely,
Barbara Berry

Date: Friday, August 18, 2023 2:30:34 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Good Afternoon:

I am writing in support of the proposed rules as stated here:

https://www.wildlife.state.nm.us/download/commission/rule-development/BEAR-AND-COUGAR-RULE-PROPOSED-CHANGES-SUMMARY_2nEd_08032023.pdf?fbclid=IwAR3QVn5B_ytJ9I3vkbqy0eBMBpyy730ErVO3HWVtM55pDzRdh7Ns1cacOxY

Bear and Cougar hunting is an important part of overall wildlife management in our state. In addition, hounds are an essential tool in this effort to manage bear and cougar. Eliminating this management tool, as some vocal advocate groups would suggest, would harm wildlife populations, landowners, and residents in general.

Coming from a family of land-owners who homesteaded the Gobernador region over 100 years ago, I would hate to see our ability to manage wildlife responsibly eliminated.

Respectfully,
Patrick Smith
Aztec, NM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Removing hound hunting from predator control will be detrimental for the states wildlife and livestock producers. The predator population was an issue before the trapping ban. Removing hound hunting definitely isn't going to help the issue.

Put some logical thought process in the decisions made. Banning hound hunting is not the answer.

I support Bear and Cougar hunting with hounds. Anyone who is an avid outdoorsman or hunter understands that hounds are an excellent way to manage these predators. The anti hunters do not want to understand these proven management methods. They act with emotion and ignore decades of results from the wildlife management through hunting. This includes the traditional method of hunting with hounds for Bear and Cougar. We must continue to follow our proven management methods to have a healthy population of either of these predators.

Please take the items below into consideration in your upcoming decision re bear & cougar hunting for the next 4yrs.

Respectfully,

Victoria Linehan
43 Hollimon Rd.
Glenwood, NM 88039

- Given the uncertainty of habitat and population estimates of both bears and cougars, the **quotas for both should be reduced**, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.
- Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.
- Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.
- The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.
- NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.
- Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the

newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.

- Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for ‘trophies’ and recreation. Ask NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

I have been hunting in New Mexico as a resident for 50 yrs. It's about time we stop allowing 10% of the people to dictate what the other 90% get to do! If we don't keep the predators in check our deer, elk, sheep, & Ibex will pay a heavy price! Which will also impact our hunting seasons. No hunter I know want to totally eliminate our bear & cougar population but it must be kept in check by reducing their numbers to a healthy limit which the New Mexico Game & Fish are trying to do! For once how about we listen to the individuals of this department that know what's best for our wildlife & hunting opportunities. Kevin M.

Dear New Mexico State Game Commission,

I am writing to you regarding bear and cougar management in New Mexico. The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and we support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, we believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

We respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Best Regards,

Caleb Schelle

Subject: [EXTERNAL] Bear & Cougar Rule
Date: Thursday, August 10, 2023 2:57:15 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am writing in opposition to the proposed "bear and cougar rule" invoking increased quotas and hunting seasons for bears and the year-round cougar-hunting season.

The proposed rule ignores the incredible stresses that prey animals are already experiencing with habitat loss exacerbated by drought and wildfires. The studies used to justify these hunting increases appear to have selectively interpreted the data in order to support their case rather than relying upon balanced studies accurately characterizing the health of the target populations. The proposed rule ignores the collateral effect that killing adult cougars and bears has on their young and would have a profoundly negative effect on the health of our state's cougar and bear populations.

I am requesting the NM Department of Game and Fish reconsider and reanalyze appropriate data and make an honest assessment of the impacts of climate change, habitat loss, and other rapidly evolving factors. Please redraft a bear and cougar rule that will genuinely protect these animals, ensuring their long-term viability.

THIS IS THE DUTY of the NM Department of Game and Fish Department: "Conserving New Mexico's Wildlife for Future Generations"

Please do not implement this new rule.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Once again I am appalled at the complete absence of biologically and scientifically based policy proposals by this state department ! Your “cave man” hunting headset and money driven policies demonstrate wonton disregard for the survival of NM wildlife. They encourage out of state bounty hunters to come to NM and kill our precious wildlife! Global warming has created multiple variables that are impacting wildlife survival . Scarcity of food and vegetation , fire destruction of habitat and soils, water scarcity wasted on fracking, gene pool reduction impacting genetics with migration obstacles to mention a

few, not including hunting kill levels. And you promise increasing those levels by 50%! This is unconscionable!

This is not a biologically driven and vested proposal! We are not a “hunting and gathering society” but a technological one. This is not about hunting for food to survive! This proposal is a disgraceful approach to Wildlife “ management” and it demonstrated no regard for NM wildlife and an obsession with the sport of hunting and trophy seeking that is destructive and an anachronism in 2023! You need biologists and genetic and climate scientists and environmental scientists to study these populations and make appropriate recommendations! I will do everything in my power to update, educate and revise your mission and policies bringing them into this century!

This proposal is unacceptable and an uneducated

and damaging idea that will have major long term impacts on irreplaceable wildlife in the context of biological diversity and species loss! And all this to cater to the mentality of hunters , trophy seekers and economic gain.

I cannot stress enough how wrongheaded and uninformed this proposal is and the severe negative impacts it would have on New Mexico’s magnificent Wildlife!

I live along Rio de la Plata which serves as a dispersal corridor for black bears, mountain lions, bobcats, deer and other wildlife. I enjoy seeing the wild animals even though a bobcat decimated my poultry and one morning a blonde black bear was on top of my chicken coop. When someone murders one of these fine wild animals I am deprived of the opportunity of observing and enjoying these animals alive and thriving in their natural habitat and the ecosystem these animals operate in are deprived of the services each individual provides. So stop the killing! New Mexico has *Cannabis* revenue now. We do not need the revenue from selling killing licenses! So just stop it. Stop the killing. Stop pandering to the psychosexual perversions of those who enjoy inflicting fear, pain and death on innocent, defenseless animals. These people are serial killers and it is only fear of consequences that keep them from practicing their sadistic arts on humans instead of non-human animals. I count on you, as the public servant of the Taxpayers, to do the right thing. Thank you.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To the Department of Game and Fish:

I live in New Mexico and spend a lot of my life in the outdoors. I love to backpack, bird watch, and hike. My husband is a hunter. But he hunts only for food, never for trophy or sport. I am writing to express my grave concern about the proposed new rule for bear and cougar hunting.

Bears and cougars are important animals in New Mexico. Because of their importance, ecologically and culturally, along with the uncertainty of population estimates for both species, their *kill quotas should be reduced*, not raised.

It is not just that these animals are important to us, it is their own intrinsic value. Bears and cougars are highly intelligent species. They are devoted mothers who spend up to 2 years raising their young and have complex social hierarchies that are easily disrupted through trophy hunting, creating social chaos that drives more conflict with humans.

Accurate population counts are vital to sound management, but obtaining an accurate count of either bears or cougars is very difficult. In fact, the current health and sustainability of both species in NM are entirely uncertain. There is no management plan detailing measurable objectives for these species. While a handful of studies were done to estimate population density in several areas, data was only collected for a short time. Such snapshots in time tell us nothing about the population's growth rate or trends. There has also been no external review of those population estimates by independent, outside experts.

This proposed rule is out of touch with both the hallmarks of good science and the conscience of the vast majority of New Mexicans. Our state's wildlife deserves better. Game and Fish must apply the precautionary principle and cut, not increase, hunting quotas and seasons to ensure bear and cougar populations are not negatively affected.

Thank you for your time,

Janie Chodosh

Hello,

Humans have terrorized and occupied nature since the dawn of time. However the New Mexico State Game Commission, New Mexico Department of Game & Fish, Bureau of Land Management, and National Forest Services have worked for decades to protect and maintain a healthy ecosystem for future generations utilizing the best resources we have available to do so. I have sadly accepted that none of these organizations have the guts to stand up for New Mexico citizens who struggle to enjoy what little of the prime hunting grounds are left to enjoy. Big for profit ranches pull political strings in order to raising factious signage & locking gates and bait game away from public lands without consequence; an example being the Express UU Bar Ranch and it's constant attempt to claim White's Peak for it's out-of-state clientele for example. But this rule review isn't in regard to the bad politics that plagues NM's Sportsmen and their ability to practice their craft. This ruling is in regard to the tools in place to assist with the management of a wildlife population. The use of hounds and trained dogs in hunting is written in the history of game hunting because it works. A rule change to minimize the ability to utilize canines in this capacity decreases the success rate of those hunts and hence will cause an undue burden on other organizations to manage the targeted game. Since 2019 citizens have found the outdoors as a refuge for the indoors and outdoor enthusiasts flocked to our open spaces and hiking trails to escape mask requirements. Without a plan in place to manage and maintain predator species, of which trained canines are utilized to track, we are putting the general public at risk with a larger population of predatory animals in nature. Take away a tool used to improve the success of a hunt and you are increasing the population of that species, in this case predatory species which do not have the best reputation of human interaction. Restricting a proven resource which would decrease the success of sportsmen means you're have to rely on the NM Department of Game & Fish to maintain those populations. And please show me where those man hours and funding are coming from; not big ranches like the UU Bar where NM Dept G&F already struggle in the policing of their encroachment and intimidation on NM's Sportsmen and which probably get tax rebates from the NM Legislature to operate hence taking from NM residents plates twice over. Most Country Sheriffs are busy fighting crime that is seeping out of larger communities into rural NM so who does that leave to pick up the burden. Who is going to raise their hand for decreasing the successfulness of a bear or cougar hunt when a family is attacked by a predator? None of this makes sense...

Respectfully,
Marcos Roybal

July 19, 2023

To Whom it May Concern:

I understand that this Friday, July 21st 9am - 5pm MT, the NM Department of Game and Fish is hosting a public and virtual gathering to hear comments to help inform their proposals for new rules that will govern the hunting of bears and cougars for the next four years. The NM Game Commission will then vote on these proposals this Fall, deciding the fate of hundreds of bears and cougars.

Since I work full time, I am unable to attend this meeting.

Below are comments that I would like to provide.

I am concerned that bears and cougars will be listed on threatened or endangered lists due to over hunting.

Last month USDA NRCS expanded their work on wildlife conservation. The State of New Mexico has funding to create wildlife corridors within the state. Increasing the number of kills for bears and cougars contradict wildlife conservation.

Given the uncertainty of habitat and population estimates of both bears and cougars, the quotas for both should be reduced, not raised. Kill quotas for both species have been unjustifiably high for many years.

Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.

Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.

Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.

The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.

Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.

Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophies' and recreation. Please consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

To kill simply for killing is incomprehensible.

Sincerely,

Amy Louise

Hello,

I want to submit a comment on this issue. PLEASE PLEASE PLEASE DO NOT raise the hunting count. These animals have enough of a hard life to survive. Between the fires and Highways plus population taking their territory this would deplete numbers even more drastically.

Thank you reaching out to the public to voice our concerns.

Hope this DOES NOT pass.

Sincerely,

Concerned Nature Lover.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

The proposed kill quotas for both bears and cougars cannot be scientifically justified. In fact, how was this determined?

No consideration has been made for rising temperatures, extreme drought or habitat loss from catastrophic fires.

Bears and Cougars both evolved to be self-regulating. There are not too many. But overhunting can cause them serious harm and damage.

We need to make sure that Game & Fish exercises extreme caution when calculating kill quotas to ensure the populations are not negatively affected.

I support hunting bear and Cougar with hounds. Any avid hunter or outdoorsman knows that hounds are an excellent way to help manage these predators. Anti hunters do not comprehend these proven hunting techniques. We need to continue our proven and successful efforts to have a healthy population of both these predators.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am not a bear or cougar hunter but I like to hunt deer & elk. If predators are not managed properly it won't be long until there won't be any deer or elk. Remember a full size cougar will consume a deer per week and a mother with cubs will consume one & a half deer per week. I have seen a black bear kill a cow and eat it in a week and a half. Remember; the only way a predator can be managed properly is by man. Take hunters out of the equation and you will not have any deer or elk. NM is trying to bring back the prong horn's at great length. If you don't manage the predators you can forget it.

Thank's for your time,

Greg

To whom it may concern, I am a NM resident and I'm of the opinion that the upcoming changes should best be managed by the following.

Rule 1 - Yes

Rule 2 - Disbanding Zone 7 - Yes

Rule 3 - They absolutely need to buy a tag to harvest a lion or bear

Rule 4 - Yes, increase harvest limit on bears.

I also STRONGLY support the removal of meat from the field for lion & bear.

Respectfully,

I know it's not what the topic is I actually think they're all pretty good but it's become a concern that a majority of the comments were from anti hunters. I'd like to believe the state would leave it science based and take emotion out but seeing how the trapping thing went just figured I'd say how detrimental it would be to both predator and prey populations if they were to ban any type of predator hunting. It would make this stage just as terrible as we're seeing washing and California are now. I just hope you keep it out of the hands of our easily swayed spineless Governor& politicians and leave it to the biologists and other qualified folk.

Letter from a Houndsman

Hound hunting for bears and mountain lions in New Mexico is crucial for population management and the overall well-being of the state. By carefully regulating these populations, we can maintain a healthy balance in the ecosystem. Banning hound hunting could lead to overpopulation, which can have detrimental effects on both wildlife and the state of New Mexico.

Hound hunting allows for selective harvesting, targeting specific bears and mountain lions that may pose a threat to human safety or livestock. This helps prevent conflicts and ensures the safety of communities. Additionally, hound hunting provides valuable data for wildlife management, allowing researchers to gather information about population size, health, and behavior. This data is essential for making informed decisions and implementing effective conservation strategies.

If hound hunting were banned, the bear and mountain lion populations could increase unchecked, leading to overpopulation. This would result in a strain on their natural food sources and potential damage to the ecosystem. Overpopulation can also increase the risk of human-wildlife conflicts, as bears and mountain lions may encroach on human settlements in search of food. This could impact the safety and well-being of both residents and animals.

In summary, hound hunting plays a crucial role in population management for bears and mountain lions in New Mexico. It helps maintain a balanced ecosystem, prevents conflicts, and provides valuable data for conservation efforts. Banning hound hunting could lead to overpopulation and negative consequences for both wildlife and the state. Responsible and regulated hunting practices are necessary to ensure the long-term sustainability of these populations and the overall health of New Mexico's natural environment.

I know that you have received emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

New Mexico Dept. of Game and Fish:

It is unclear to me why NM is authorized to kill 10% of the state's bears and Cougars every year.

To up that percentage to 25% is destructive.

Why do we humans have to kill them at all?

We aren't doing that to provide nourishment so that humans might eat!

Surely that is the purpose of the Dept of Game and Fish: To manage and provide food for humans!

We don't eat bear or cougar. So stop killing them as "recreation". They are an essential part of the eco-system.

Thank you for listening.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Good Evening,

My name is Ryan Trimble. Thank you for your continued service to the lands and wildlife of the Land of Enchantment, and for the opportunity to share my thoughts and concerns with you.

As a native New Mexican and someone who has enjoyed and explored the great state, I am writing to strongly encourage you to revisit the new bear and cougar hunting hunting quotas.

Wildlife management needs to be based on sound science, and should not be rushed to appease any one group of stakeholders.

These keystone species play a critical role in New Mexico's incredible ecosystems, and to expand hunting quotas at this time would negatively impact the populations of each.

Please give serious consideration to not expanding hunting opportunities, or at the very least, pausing the consideration until more robust data and analysis can be procured.

New Mexico's wildlife belongs to us all. It is my hope that viewpoints from all stakeholders, not just consumptive users, will be heard and respected.

Thank you,

Ryan Trimble

Why is the Agency listening to political pressure rather than biology and science? Game animals do not fare well under management using political ideology instead of sound age old well documented science & conservation management practices. Your Program Directors and Biologists should know this well and should stand firmly behind their craft and education on this and not be swayed by political agenda and activism. NM has lost public land trapping, and predator numbers easily reflect the impact that is having on game animals and the increased conflicts between the public and private land users. This is easily statistical data that is tracked and a matter of public record. Taking another well documented management tool from the system based solely on activism and unfounded claims and data is not how an Agency should "manage". Getting rid of hound hunting is a terrible idea. The State is watching the steady decline of Mule Deer in some regions due to predation and birth rates that are lower 1. Due to the increased stress Mule Deer feel and therefore have a lower conceive rate due to the stress or the natural stress induced aborting before full term. Mule Deer are sensitive to predator stress in that regard. Then Hunters and the Outfitters know very well that Bears are a primary predator of Elk Calves more than any other predator in the woods and the high population numbers are steady and well established, easily handling the current and increased quotes. Mule Deer suffer a large amount of predation from Bears as well, more than many people actually think.

The use of hound hunting is essential to management of numbers of the predators AND the numbers of other Game Animals in NM inventory. Not to mention the revenues that it creates to fund more study programs and management tools. Activists offer no replacement to those revenues and cutting out these current tools that the Agency uses to fund resources and programs and grow Game Animal numbers by reduced predation. Why is the Agency considering allowing Activists to dictate the reduction of revenues and decreased resources the Agency can continue to use and study and protect ALL Game Animals under their Charge? Every state, without exception, that has banned hounds has suffered the consequences. Please consider reinstating Trapping programs as a management tool both for management but also revenues and resources the Agency can use (by check stations that give data like population, size, health, ages etc of harvested animals that otherwise cost the Agency AND the tax payer huge dollars to otherwise collect) Due to Houndsmen and Trapping there are less conflicts of predator type animals with the public at large and this is a benefit to both the public and the Agency and the health of all remaining animals to include higher recruitment for Mule Deer and Elk populations.

The Agency would do well to stick to science and management rather than to be influenced, intimidated, and threatened to be managed by political agendas that are not based on historical data or any kind of successful management data to back it up. Hunters, Outdoorsmen, Houndsmen, Outfitters are the tools that provide large amounts and non-tax

payer funding, give huge amounts of volunteerism, and resources to the Agency that the Activists will never bring to bare for the cause. They only want to strip away the tools the Agency has to manage successful well funded programs and they want the hunters and outdoorsmen out of the woods - that's their only agenda. They are not offering Science or Management, nor resources, funding, or true solutions to long term health of ALL populations in the woods. Do not be intimidated by activists and get rid of Hound Hunting in NM. Furthermore, the reduced Cougar numbers in Zone Q is a horrible idea. I hunt numerous months in that zone and I can assure you the Lions are healthy. They are eating BigHorn Sheep, they are hammering the Barbary Sheep Population and birth rates there are extremely LOW... I have seen Lion Kills of Both Sheep Species and Elk carcasses in that Zone nearly every time I go there. Especially if the long term goal of growing the Big Horn Population is a stated Goal - reducing the Lion Harvest numbers for Zone Q is a horrible idea... it in reality should be INCREASED by 10%-20% in my opinion !

JJ Sutton, CPS, CMAS Lic NM Guide,

To whom it may concern :

I am a hunting guide here in the state and I am against the hunting of said animals with dogs. These animals are harassed year round as these outfitters use out of season times to train their dogs . These hounds also suffer catastrophic injuries and even inhumane deaths all for profit by these so called Houndsman .

There is no fair chase given to these predators.

And on one more note Game Cameras are also not fair chase .

Please outlaw these activities.

Thank You CMO

The banning of bear & Cougar hunting would be detrimental to the life of other wildlife because hunters help to mitigate the predator populis. I'm for hunting these beautiful animals to help play a part in preservation and conservation of hunting. I believe that it's my right to hunt and gather by means within the law. The ban of such animals would also hurt ranchers who build a living by using the BLM resources to help produce beef for local areas. We also have to look at the dangers this ban would pose in cities and towns that are in close proximity to the natural habits and camp grounds that are used by the non hunting community. Please don't ban hunting these magnificent animals as an avid hunter I also consume the meat from both species of animals. Thank you for your time.

Dear New Mexico State Game Commission,

I am a fair chase bear hunter and would like to continue to be able to do that. Fish and wildlife resources are the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. Science based management has resulted in good sustainable populations of bear and cougar in New Mexico. This management has included reasonable harvest of these animals. I support legal bear and cougar hunting as an appropriate management tool. I believe you should continue stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully,

Gerry Engel

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I would like to support the continued use of hunting to manage populations of predators in New Mexico. The use of good wildlife biology as practiced by good wildlife biologists in the department is the only sensible way to keep predator/prey numbers balanced. As a former member of the Game Commission I know that such decisions must be guided by a reasoned scientific approach rather than a wall of sound generated by zealots who simply wish to advance their anti-hunting agenda. They have no regard for health of the ecosystem or the tremendous benefits to people who utilize the outdoors for recreation, food sourcing, and agriculture. These zealots completely dismiss any opinions other than their own and as such are sanctimonious elitists. However they do generate a huge amount of noise which I hope you to discount. I furthermore urge you to continue allowing the use of hounds and dogs to aid in the taking of game as well. The use of dogs to help humans is a tradition dating back hundreds of thousands of years. To imply that partnership is no longer valid is an insult to dog owners and dogs as well. Thank you for hearing me out. Robert V. Hoffman Las Cruces NM

Greetings.

I live in Oregon but hunt in New Mexico. Simply put, leave bear and cougar hunting alone, here in Oregon the science has played out and bears and cougars WILL BE MANAGED. 100% of our liberal legislature agrees with the science. Our government now does our states cougar hound hunting and black bear killing with snares and bait, those bear and cougar are incinerated and landfilled. How is this management? It's not, this is CONTROL!

You need to include government in your ban proposal if you proceeded forward like Oregon and California has towards communism!

Mike Martell
Big Game Wildlife Manager

Hello,

I'm writing to let you know that:

- 1) I oppose your bear and cougar quotas and long hunting seasons.
- 2) I would like kill quotas to be significantly reduced to protect our valuable wildlife.
- 3) Additionally, I would like a certified independent consultant to perform the census on these populations prior to any rules being proposed. Your decisions should be based on the science, the numbers, and the facts, without any possibility of undue influence.
- 4) I opposed to the killing of wildlife.

Thank you,
Sara Hufford

Dear New Mexico State Game Commission,

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and we support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, we believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time. The desire to protect and manage these species in a respectful way is every responsible hunter's desire so that we may coexist with these species for generations to come.

We respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully,

Brett Rezek

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To Whom It May Concern:

In this era of increasing understanding of the critical role of apex predators in an eco-system, I find New Mexico's Game and Fish's current consideration to increase so-called harvest limits of bear and cougar in New Mexico to be both outdated and unscientific. I unequivocally object to increasing the harvest limits of either species, and I believe most people in the state feel the way I do. Please don't allow a very small amount of people - cattle ranchers and the few hundreds who buy these permits - to dictate policy that the rest of us would vote against were we given the chance. Some day in the not too distant future, we will look back on these rules as shameful and ignorant.

Good morning,

As a long time hound hunter, small game hunter, and big game hunter, I am writing today to say that I support the scientific approach to predator management in New Mexico. I was a registered guide in New Mexico for a few years and spent a lot of time in the field. New Mexico is one of the best and well managed states I have ever hunted and the only way to keep it that way is to manage by research, boots on the ground, hunting reports, and game studies. As stewards of the land we cannot allow groups and people to persuade decisions based on emotions and beliefs. These decisions will be detrimental to the future of our wildlife and outdoor/hunting opportunities for our youth. Please do not ignore the facts, the research, and the future to appease groups that only have one agenda.

Thank you for your time

Sincerely,

Jason Myers

What are u doing?? What possible rationale is there for killing more wildlife. If NMGF has no clue as to the total number of these animals present, then they have no idea which parts of our forests have how many animals. How can NMGF assess impacts and unintended consequences if NMGF doesn't know the population or it's distribution. Sounds like USFS prescribed burn policy! Let the animals just be.

And why not make the hunt more like a hunt than a roundup using packs of dogs to run the poor beasts into exhaustion so the 'hunter' can blast it at short range from his ATV. Hard to call that sportsmanship, all for a machoman wall trophy. NMGF should be ashamed they have these rules and now want more forest brutality! Absolutely absurd!!

Do not do this!!!

As a NM born resident I am in favor of continued hunting of black bear and mountain lion throughout the state. I side with the biological studies over the court of public opinion on this issue. The ecosystem of the states wildlife is a delicate balance that the State Game and Fish have been charged with maintaining. Hunting of wildlife and specifically the hunting of bear and lion are part of that balance. Ignoring the science in favor of those opposed on other grounds is irresponsible.

Thank you for your consideration in reading my opinion and right to speak on it.

Dear NMDGF,

As a lifelong NM outdoorsman and hunter in my home state, I want to give my full approval in favor of responsible predator hunt programs and the scientific management proposal submitted by game department biologists.

I have hunted both cougar and bear for many years and have noted the importance of managing their populations responsibly to maintain a balance between ungulate species, predators, and deadly human / wildlife conflict.

The only change that I propose is : Non-residence should not be able to purchase over-the-counter hunting permits for bear or cougar, because I have witnessed how our state is flooded with non-residence during these hunting seasons causing quotas to be met early at the expense of resident hunters who deserve more favorable opportunity, such as is the case with other big game species such as elk, deer, etc.

Sincerely,

Dustin

Dear sirs,

I am writing you in support of sensible bear and cougar hunting in New Mexico. Predator control is an important aspect of the overall game management in New Mexico. I have 4,000 acres of leased land in Unit 2B in NW New Mexico and I find mountain lion kills of both deer and elk on the property from November thru April each year and have watched bears kill deer fawns and elk calves. It is my opinion that the highest mortality of our fawns and calves occur due to bear and lion predation. The decline of our Mule Deer and elk populations will be exacerbated without sensible hunting of both mountain lions and bears.

Thank you,
Vern Andrews

Sirs/Madams;

Please consider that Hunting is and was, and should be a continuing right for people. By no means does everyone need to be a hunter, I feel it's just that those who appreciate game management, shooting sports, and the woods so to speak should not be deprived for spurious pseudoreasonings of some who would wish all were like them.

Having been a life long hunter, I'm now 74, in my life I have had the opportunity to go on mountain lion hunts in the Gil Wilderness in the 50'-70's with my Father and his rancher friends, jump ducks on tanks in southwestern NM, Fish for Gila natives in White Creek in the 60's on 2 week pack trips at the end of school, deer and elk hunt the Gila, and learn to be self confident, resourceful, and to have a love for the wild.

Hunting is a dear part of this tradition, and at worst, bag limits should be set by conditions on the ground, not arbitrary declarations. I believe in science and the possibility of scientific management of game animals, reinforced with on site data.

Do not succumb to unreasonable and ill advised arguments.

Thank you,

Peter J Walsh

To the powers that be regarding the hunting of bears and cougars in N.M.,

STOP THE NEEDLESS KILLING OF OUR WILDLIFE !!

As a resident of N.M. for more than 40 years I strongly feel that the only shots that should be taken of the bears and cougars or any other members of our wildlife families in N.M. are photographs. Sell permits to take photographs only.

If you want to promote population control then start with controlling our human population - there's no shortage of humans on this planet.

Anyone who takes pleasure in trophy hunting should hang the heads of their dead relatives on their living room wall and leave the animals alone for the rest of to enjoy in the wild.

Hello,

I am a wildlife biologist by training, and I support smart, targeted wildlife management in New Mexico for all species, including all game species, predators, and non-game species. In regards to management of predators, and in this case specifically bears and mountain lions, I support managing species through active population monitoring, and when those populations allow for the taking of animals, I support the harvest of those predators through all currently legal harvest means including hunting (with and without the use of dogs). Managing wildlife populations is a balancing act, where choices for one species can often have ramifications for other species. Predators play an important role in all ecosystems, but if their populations are allowed to grow unchecked, there are often severe adverse effects for all other game and non-game species. I do not advocate for taking predators when populations fall below acceptable thresholds that might endanger the well being of that species, but I believe that the ability to harvest predators when their populations are healthy helps improve and or at least maintain the well being of other wildlife species that are also important in New Mexico. I firmly support the continued harvest of predators in New Mexico by all currently legal means where those populations are able to sustain such harvest.

Dear Sirs:

I am a resident and hunter of the great state of New Mexico. I am not surprised that the anti-hunters want to stop the hunting of bears and cougars in New Mexico. I think the New Mexico Dept. of Game and Fish have a pretty good handle on allowing the take of bears and cougars in the state. With the change in the weather patterns, these animals are starting to get closer to residences of people which includes young kids. We need to very careful about not allowing our responsible citizens the ability to defend ourselves, as well as to hunt to further ensure that the numbers of animals do not get too high. I think the numbers of bears and cougars has increased in the last few years. This can cause problems for small communities, ranchers, farmers, hunters, hikers, horse riders, etc. I DO NOT AGREE WITH THESE EFFORTS TO STOP HUNTING OF BEARS AND COUGARS. Thank you.

Allowing harvesting of bear and cougar in the state of New Mexico is the only valid solution to keep the numbers in somewhat of a balance with the food sources they consume. I have not seen many elk calves this year (2023) or fawns. Visiting with other hunters and ranchers have confirmed my suspicions that a large portion of these young elk and fawn are being consumed by too many bears and cougars. Thus we have seen a decline in the last several years in the overall populations of deer and elk. The one place deer seem to be doing well are within town limits. However this has also drawn these predators into town with frequent sightings/encounters among individuals as well as some public discord it causes. Within the last couple of years one of the local schools kept the children in from recess due to sightings of a cougar close to the school that day. Not too infrequently we encounter pets who have survived an attack by a cougar, but unfortunately many do not survive the attack. There even has been more human and cougar/bear encounters when out in the forest trail systems. There was a man in Pinos Altos, NM who was killed and partially eaten by a cougar within the last 10 years. The biologist who work for the NMDGF have the best data to establish the harvesting quotas for the wildlife within our state. Responsible stewardship of the many species of wildlife within NM is best served by the NMDGF with knowledgeable people chosen from the public to serve as committee members. Radical groups without sound knowledge and common sense of the wildlife ecosystem within our state need to be countered in their false claims to try and limit the management decisions of our NM wildlife.

It would be a major mistake to NOT to continue to allow the use of hounds to manage the population of bears and cougars. Management of these species is essential for the successful management of many other game animals whose numbers are greatly effected by the numbers of bears and cougars. Management of bears and cougars will also play a major role in minimizing the interaction of these species within cities and populated rural areas.

To whom it may concern.

I wanted to take this time to comment on the proposed bear and cougar rules for New Mexico. I propose that any quotas supported by the NM game and fish wildlife biologists to be true and exact. NMDGF pay wildlife biologists to study and maintain all wildlife conservation efforts within the State of NM. I propose the NMDGF continues to take the advise of their hired biologists on bear and cougar quotas set forth each year. Basically I believe in what the department is doing to have a healthy wildlife population and any attempt to close hunting in any way, shape or form of any NM wildlife is just an attempt to allow the populations to explode.

Thank you,

Kevin Kelleher

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear NM Game and Fish staff. Please read below and enter it in the public record of the October 27, 2023, Game Commission meeting.

Some important information regarding the proposed kill quotas for bears and cougars in New Mexico:

The most destructive species known to Man is Man. Not cougars, not bears. Man.

Cougars and bears play critical roles in the maintenance of the natural Biosphere, of the health and well-being of the plants and animals that exist here in New Mexico. Killing large numbers, actually, killing any number of bears and cougars upsets the natural balance. Man upsets the natural balance. Game and Fish upsets the natural balance.

Rethink your proper roles here, humans. At the absolute minimum action, seriously reduce the kill quotas. Or, better still, eliminate them, let Nature do the balancing, not humans. Humans are just one species here, and not a particularly beneficial one in the natural world.

Subject: [EXTERNAL] Bear and Cougar Quota
Date: Thursday, July 20, 2023 7:43:01 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hello,

I'm writing to express my concern about raising the Bear and Cougar quota in New Mexico. I'm a contributing member of the Mountain Lion Foundation, which tracks mountain populations across the country. According to their research, mountain lions are not at a sustainable level in New Mexico. Raising the quota on kills would put them even more at risk.

Please consider my voice and the voices of others before making a decision.

Thanks for your time in reading this.

Scott Hendershot

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise. Thank you.

Date: Wednesday, August 23, 2023 2:49:47 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Dear New Mexico State Game Commission,

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management. While I don't reside in NM, I support predator management everywhere as a management tool for the world we live in. Legal bear and cougar hunting *is* an appropriate management tool. I hope you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully,

Mary Graves

Good morning,

I am thankful for a Fish and Game Department, like ours in New Mexico, that follows the science. I am a scientist and a hunter and believe from attending the meeting in Roswell and follow up research that the NMDGF is living up to the ideals of the North American Model of game management in this decision. I am in favor of the rule changes, and in pursuing more similar studies in other GMUs across the state.

Thank you,

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

In this time of mass extinctions, mega-fires, and persistent drought we need to prioritize the protection of wildlife and wild places over human recreational opportunities.

I have a Masters in Biology, a Bachelors in Wildlife Management, and see nothing in the proposed rule changes that supports an expansion of seasons or increased kill quotas to promote the health of bear and cougar populations, their prey, or the ecosystem.

New Mexico is not a game farm and should not be managed as such. Any changes made to the Bear and Cougar Rule should prioritize the protection of biodiversity over recreation or align regulations with Fair Chase hunting principles by banning the use of dogs in cougar and bear hunting. Do not expand seasons or increase kill quotas for cougars or bears.

Sincerely,

Melissa Amarello, MS Biology

Hello,

I am writing in regards to the proposed change in harvest limits of bears and mountain lions. I am a 27 year old hunter from Northern California currently going to school to obtain my degree in wildlife conservation. During my research of the bighorn sheep for a course project I found that the number one cause of mortality among sheep is mountain lion predation. My states population of deer and sheep species are on the decline due to an excess number of preedators in the area. Mountain lion hunting was outlawed in 1992 and the use of dogs for bear hunting became illegal in 2013. Attached is a research paper that has some graphs one of which specifically showing New Mexicos herd numbers of bighorn sheep before and after population control of mountain lions. The results speak for themselves. I do not believe putting more restrictions on predator management will help anything but the anti hunters sleep better at night.

As a nonresident I appreciate the State opening the comments for the bear rules, I don't have much input on the cougar rules, other than I'm finding a few more deer carcasses than in the past.

Having certain units that open and allow dog use to any legal weapon before the archery elk and deer seasons seems to influence the archery hunts and is pushing elk and deer from public land onto private prior to the season opening. My comment would be against having an any legal weapon bear season prior to archery seasons or allowing dog use prior to archery seasons. Either one of those options will improve the early archery hunts in North Central New Mexico. To me it would make sense if the post archery season bear hunts were the only any legal weapon hunts and if bear populations were a concern open the spring season again. I would apply for a spring bear tag.

My opinion on harvest, sex, and zone limits is that the biologists need to determine those.

Thanks for the opportunity to hunt and comment on the hunting in your state.

I think it's important that we continue to hunt predators. It is vital with regard to population control. Additionally, cougars unlike other predators, will sport kill deer. Much like a house cat that isn't hungry, but will kill anyway for sport. I've noticed that I've seen less deer in areas that used to hold them greater numbers. The only way to effectively hunt cougars is with dogs. This practice should not be banned.

Thank you.

Please consider this appeal to continue the practice of responsible predator hunting in New Mexico. Our state game biologist and department do an excellent job of scientific management of wild game to include predators all within our traditional norms.

I know that there is a loud voice of largely out of state people trying to curb our hunting traditions here in New Mexico. These people have significant financial backing and they are not working in the interest of conservation nor our wild animal population.

Thank you for your consideration.

Greetings,

I have been hunting in our state for 30 years-- mostly elk. I was glad to find out about this upcoming issue from New Mexico Wildlife.

I strongly oppose bear and cougar hunting. Apex predators play a critical role in our environment that is increasingly stressed out due to major changes. I was just in the Santa Barbara divide up at Truchas lakes two weeks ago, astonished to see the bark beetle damage. Plus, there has been so much habitat loss due to the fires.

There is no biologist who can determine the impact of these changes on apex predators. With climate change, we are in a totally new paradigm. Plus, we have a non-soon, not a monsoon. There's no question that the loss of forage due to the burn will impact bears. We cannot continue on the same path that we have in the past. That very kind of mentality-- not being up to date with current data due to climate change, lead to the fires that we had last summer.

Hunters who ignore this reality and want to continue just as things have been are not paying attention and do not have the interest of our wild lands at heart. Plus, people are not hunting bear and cougar to fill their freezer like deer and elk, which I hunt. It's all about trophies-- which is an ugly.

As a hunter, as someone who truly loves to hunt, I urge you to ban apex predator hunting. It doesn't belong in today's climate change habitat loss world. These predators need all the protection we can offer them.

I would also add that there are many hunters who feel just as I do. Don't be fooled by the vocal few.

Sincerely,

Marc

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Support the science based recommendations of professional biologists. The voices wanting to stop hunting are the same type of voices that crushed logging. Now we see thousands of acres at a time burn with increasingly hot fire. These people intend well with their view and emotions but they are wrong. Let professional science based management set the Rules and not emotions. When a mountain lion was found at an elementary school in Arizona, the professionals had it removed. The animal protection voices led a campaign to fire the Director of AZGF and the Coronado NF Forest Supervisor. These people would have never said a word if that lion had killed a small child. Reject management by emotions and act on the good science and experience of the professional Department managers.

Sincerely,
Don De Lorenzo

Subject: [EXTERNAL] Bear and Cougar Rules Public Comments
Date: Thursday, July 20, 2023 1:54:31 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Please protect the wildlife you are responsible for. Kill quotas should be reduced for both bears and cougars, not raised. Both species can self-regulate their own populations and do not require human interference. Additionally, the hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. There has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

Further, NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.

I personally oppose any killing for "fun", "sport", "recreation", or "trophies". Please consider policies that are humane and responsible instead.

Thank you!

Dear New Mexico State Game Commission,

While I'm not a New Mexico Resident, I would be a hunter who would come hunt black bear and mountain lions. I support the research and the changes recommended.

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and I support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, I believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully,

Rusty Brixey

Hello, I am writing regarding the "Bear and Cougar Rules". I fully support the hunting of bears and cougars by all currently legal means. This includes dogs and electronic callers. Use of hounds is not only a longstanding tradition, but also one of the only effective means of managing populations, especially of elusive cougars. Managing the predators is important to the health of all other species as well. The use of electronic callers is also a safety issue for hunters as the predator can be called away from the hunter's actual location. I would also be in support of raising the current quotas on these two species.

Thank you.

Hunting has been a part of the American tradition since our fore fathers came to establish a new country.

It has been a means of supplying table fare for our families. And a way of proper conversation.

It has been proven by state biologists; without proper management of wildlife. The balance of nature becomes out of balance. And wildlife over populates their habitat.

Food becomes hard to find for wildlife. And soon they wonder into populated areas. And endanger the public.

I recently was working on a customers property in the Sandia Heights area in Albuquerque, NM.

The property has apple trees and cherry trees in the back yard. While cleaning the area. We noticed a large pile of bear scat around the apple trees. Only 12 feet from the back entrance of the home.

Pets go missing and often their remains are found after being consumed by cougars and bears. The question is what happens if hunting and trapping are outlawed?

Putting the public in danger is not a priority? Proper control of these animals is critical! Over grazing of the habitat. Leads these animals to seek food such as pets, live stock and possibly the human population.

Nature has always had a way of balancing this. But, it is out of balance. What predators keep bears and cougars in check with their habitat!

The answer is proper conversation through controlled hunting practices!

Look at Raton NM a few years back. A woman was attacked and killed by a bear. That broken into her mobile home.

The Philmont Boys Ranch has had bear attacks on boyscouts camping in that area.

Anti hunting groups do not consider the danger and loss that occurs when Winnie the Pooh and Tigger can't find food. Because there are too many of them and they no longer stay in the natural boundary of nature.

Please listen to our biologists and those who know the importance of proper wildlife management!

Thank you for your concern in maintaining a proper solution. That has been in place for generations!

Joe Valdez

Being an out of state hunter from Texas, Myself and my family have enjoyed hunting in New Mexico for around half of my life (20 years). We've hunted mule deer, elk, Coues Deer, bear and cougar and enjoy everything New Mexico has to offer. To allow non-hunting activist to stop bear and cougar hunting would be devastating not only for the local guides and economy, but also to the out of stators, and not to mention all of the other big game wildlife New Mexico has to offer that would suffer by those populations getting out of control.

Thank you

I am in favor of all current rules and hunts applied to bear and cougars. If anything, there should be more cougars and bears knocked down in some units. If bear and cougar quotas get any lower, big game numbers will be affected drastically. People from out of state, never go out hunting or in the wilderness should have no affect on how the state handles quotas or dictate any laws or rule changes.

NMDGF needs to follow science based recommendations in setting management and harvest regulations. Regulated hunting manages populations and provides a deterrent to animals becoming habituated to humans and population centers. It is an accepted fact that exact population numbers are impossible to determine with current science, however this should not preclude managing the animals.

I support set seasons and current legal methods of take, including hounds.

I do not support indiscriminate killing in support of the livestock industry. However, animals in the act of killing livestock or pets should be removed or killed as necessary.

Thank-you for your consideration.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

The hunting seasons for both bear and cougar need to remain the same. A system is already in place through New Mexico Game and Fish to monitor the amount of Cougars and Bears in Hunting Zones that cover the entire State. Therefore both species are already being managed successfully I believe throughout the entire State.

I grew up in Unit 2 for example. Especially in unit 2A growing up as a kid in the 80s and 90s and hunting with my Grandad and Uncle every year (when we would be able to purchase OTC tags at the local Handy Bait and Tackle Store in Aztec) we would see numerous amounts of deer and even elk, but definitely more Bucks than anything. Now days you take a drive through those same hills you still see deer and elk but definitely not the number of Bucks and overall deer and elk in general as I used to see.

I believe this is in big part to the Mountain Lion population that has grown here just in the NW portion of the State (probably state wide). If a cougar takes out a deer or and elk a week to survive our numbers of deer and elk are going to decrease within the State dramatically as I believe they already have up in this NW area of the State.

If hunting seasons are even more limited on bears and cougars you are going to see bear and cougar populations rise and deer and elk population continue to decrease.

Thank you for your time,
Chris Spencer

Dear New Mexico State Game Commission,

It has come to my attention that a large number of comments have been received and directed to your commission, from well intentioned but largely uninformed citizens who have argued for the cessation of Bear and Cougar hunting. This is in direct opposition to all scientific data and population estimates based on true research.

I would strongly appeal to you to please not give in to the emotional and uninformed plea from these people to stop hunting of both species. Currently our state enjoys healthy numbers of both bear and cougars as they are correctly and intelligently managed by the NMDGF. To change these two species to totally "protected" would result in devastation of our cattle ranching industry and our deer and elk herds as well. Both of which currently face tremendous pressure from a burgeoning wolf population. Ultimately this would of course seriously reduce the Apex predators themselves as they would run out of prey species, turn to livestock and then be eliminated to preserve private property of the ranchers.

The changes as proposed by NMGFD to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our department biologist and the recommendations developed from their science-based data such as non-invasive scat/hair sampling, remote/trail cameras, GPS collars, hunter surveys, landowner reports and other traditional measures.

Thank you for your sincere consideration of this request.

Respectfully,

Hi my name is Missy Hale.

I have been an avid hunter for many years in NM. I am for opening up the bear hunting in August again. I also think it would be great for those who draw a wildlife management tag to be able to hunt cougar and bear.

I am also for hound hunting. They took away our trapping rights and those of us that live in the dry desert country is the only way to protect our livestock from lions and bears is with hounds. I'm not sure what's on discussion for cougars but I'm sure they are coming after our hound hunting next.

Not sure why you don't have a depredation list on problem bears and lions where the state could make revenue from them instead of just having a govt. Hunter dispatch them. Without our bear and lion seasons they will become a bigger problem as people are moving out into their habitat. Bear are loosing habitat daily by new development in many areas in NM so in places their numbers need to be kept in check so there are not as many problem bears.

I hope our seasons stay open and we can enjoy hunting for years to come.

Thank you

Missy Hale

New Mexico Department of Game and Fish:

Hunting as a method of putting food on the table has been a way of life in the United States of America since our country was formed. Proper conversation through controlled hunting of Bear and Cougar practices is the key to proper control of over population of these species.

Many people lose their pets to cougars and bears. If hunting and trapping are outlawed, how many more family pets will be consumed by these animals if their number increases as a result of laws that prevent the hunting of bears and cougars?

It is in the best interest of New Mexico and its residents for public safety and the safety of their pets, to not outlaw the hunting and trapping of bears and cougars in the State of New Mexico.

Thanking you in advance for maintaining a proper solution, that will not outlaw the hunting and trapping of bears and cougars in the State of New Mexico.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.

Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.

The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

Subject: [EXTERNAL] Bear and Cougar Topic Meeting
Date: Tuesday, August 15, 2023 8:52:10 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hi,

My name is Vince Martinez, I was unable to attend any of the meetings this week but I wanted to give some input on some changes that I would like to see happen to our bear and cougar hunting.

First I would like to start off with bear hunting. I feel that it is unfair to us residents to all of these out of staters that come hunting to our lands and can just purchase a tag over the counter. I would like to see some changes done to that and make it for out of staters to have a draw system like the way Utah does and only allow a few out of state hunters to draw a pursuit only tag or a kill tag and slow down the amount of out of staters that come hunting on our lands. I feel that this should go for mountain lion as well. It's sad to see your favorite hunting spots get flooded with out of staters come August and September.

Another note that I would like to make is to allow a spring/summer bear pursuit only season for NM residents. I feel that it would produce more income for the state allowing houndsmen get out and train their dogs only. No harvesting in the spring/summer only a pursuit season.

Lastly for cougar, something needs to be done and changed with taking out unit 6 from the current zone it is in and putting it back to the way it was before the changes. It's not fair to the other houndsmen that hunt unit 6 and it gets closed right away because of all the harvesting they do in 50,51 and 52.

I'm hoping this email falls to someone who has an open ear and is willing to help out to make this state better for generations to come for future hunters and houndsmen. I have also been seeing a lot of talk about the anti hunters that attended the meetings as well and it kills me and fellow New Mexicans, houndsmen and hunters that this is happening to our beautiful state as well. We have some of the best hunting in the US and a lot of houndsmen come out to this state to hunt. It brings in a ton of revenue for the state also. Look what the anti hunters have done in the states that they have moved from in California and Colorado. They have multiple attacks on humans each year from bears and cougars. Why we ask? Because of them and stopping the population management that we provide. They're out of control in those states and not to mention all of the inbred animals because they are overpopulated. Please don't let this amazing state turn into another California, it's sad because I see it turning this way not only in hunting but all around the state.

Thank you,
Vince

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I have been watching how New Mexico has managed the Bear and Cougar population and it is very impressive. New Mexico has a healthy population of both species and provide very good opportunity for harvest. I am from Nebraska and will be coming to New Mexico to hunt Bear with hounds and horses in the Gila Wilderness area. Hunting with hounds in wilderness is special and adds a level of excitement that is hard to explain. The harvest is secondary to the hunt.

Hunting Bear and Cougar with hounds provides a valuable tool for management. No one wants to maintain a healthy population of Bear and Cougar than the hound hunter and I hope this tradition will continue in New Mexico. I want to bring my Grandkids to hunt someday.

Thank You,

Matt Holsten

To whom it may concern.

There's allot of numskulls in this day and age that DO NOT understand wild game CONSERVATION. They are being funded by radical left bunny huggers that don't have a clue either. These Bears and lions in New Mexico are being managed just fine with the State Game Department. Yes there's always flaws in any system. But these animals that aren't harvested with legal hunting of all kinds end up being a nuisance and are harvested anyway by the game department or their select contractors. Many die of starvation and disease and or predation from other Apex predators. Very much not a humane way to go. Do not bend to the crybabies that make the most noise. They know not what they do! Keep the Bear and Cougar hunting just as it is. It's a win win situation as it is now.

Thanks

Cheers,

Doug

I am totally in favor of responsible control of predator hunting in New Mexico as proposed by the biologists of New Mexico Game and Fish. To stop this hunting would be a disaster for many other game animals in this state. The explosion of predators when not controlled would lead to drops in numbers of all other game animals. The two large predators would ultimately see many more attacks on hikers, bikers, hunters and children in the woods and in cities. We have enough of that now with global warming and drought conditions. Just look at California, a state that seldom does anything right. Count me in favor of continuing responsible control.

I have been involved as an outfitter and now as retired, as an avid hunter. The need to control all predators is very important to BALANCE to the entire ecosystem.

Those that propose any reduction in taking of predators without SOUND observation and analysis are making a horrible mistake.

Predators take more wildlife than almost anything other than automobiles.

I have a brother that has had to kill more bears in the last year due to depredation (Killing his chickens and turkeys) than I have in the last 5 years. All because of the reduction in harvest over the last 25 years.

The bear and cougar populations are stronger and in some cases out of control.

NO REDUCTIONS !!! Only increases in harvest numbers of predators!!

Dear Commissioners,

As a New Mexico outdoorsman I would hope you always keep the New Mexico tradition of lion and bear hunting alive and that you don't ever cave to the anti hunting groups. These hunts are regulated and the lions and bear seem to be doing very good just the way things are.

Thank you,

David Rauber

Bear and Cougar hunting is an integral part of wildlife conservation for the entire state. Legislation or bans that tie the hands of biologists and take away critical management tools have a proven record of negative outcomes (see California). Please continue to allow state biologists to set quotas for sustainable predator harvest for the good of all New Mexico wildlife.

Sincerely,
Mike Leonardi

Bear and cougar hunting should continue to be based on scientific analysis, conducted by professional game management personnel. Anti-hunters have absolutely no business interfering with this practice! The 10yr cougar study on White Sands proved the stupidity of not managing via regulated hunting. Tell the anti-hunters their "feelings" have no place in sensible game management!

Just wanted to write you a short note stating that my family and I are in favor of keeping bear and cougar hunting as it currently is. These animals are continually increasing in number in residential areas which will only make them less afraid of human interaction. Hunting will help to maintain those numbers and lessen the push for the animals to encroach upon residential areas.

Thank you.

Good day. I am writing in support of bear and cougar hunting.

Most hunters realize the bears and cougars have no natural predators. Should our ability to hunt them be stymied by non-hunters, who in reality don't understand man's role in keeping the system in balance, it will result in unchecked population growth for both species.

Both bears and cougars, if left alone, will wipe out the deer and elk populations. Cougars kill and eat roughly one deer or small elk per week. The number of deer/elk that will be killed, should these two species be left to their own accord, will ultimately result in decimation of both deer and elk.

G. Matthew Allen
Milan, NM.

Look at Utah's laws pertaining to Bear and Cougar hunting if you want to see how a well administered conservation plans work. We have no further seasons for Mountain Lions as we have so many it no longer matters. We hunt them year round without a permit. Utah DWR collared and tracked several Mountain Lions in the Pine Mountains of Southern Utah and found they were each killing 4-5 yearling Deer a week. A spot and stalk Bear Hunt is about the hardest hunt known to humanity and the success rate has no bearing on Bear populations. Do not let peoples emotions make game laws. Let science determine the best pathway forward. No to hunting bans. SFC Ronald "Kilmore" Moore (USA ret).

I support hunting bears and cougars with hounds in New Mexico. The landscape is very rugged in our state and the use of hounds is very necessary to help control predator populations. One cougar can eat a deer a week. That is at least 52 a year. Combine all the cougars and that is substantial reduction in deer numbers. Add bear kills and habitat loss and it is easy to see why deer numbers are down. I have seen two cougars in 56 years of hunting. Not easily hunted using traditional methods. If baiting and traps are illegal how else are you going to control cougar populations without hounds? I see cougar tracks more and more and deer less and less.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am writing to protest the new ruling allowing increased number of Bear and Cougar kills as well as lengthening the hunting season.

As a resident bordering wilderness we regularly witness hunters inhumanly tracking and killing these animals with hounds. We had an incident 2 years ago where hunting dogs were on our property, we got them off, the hunters however ended up killing the bear they were tracking which was a female with a cub. The cub came out of hibernation on our property starving and in very poor shape. We contact Fish and Game and were told he would move on. The cub caused no harm and without a mother had no idea how to survive and ended up dying in our hay field. We have witnessed a similar case with a cougar cub roaming aimlessly because the mother had been killed.

These animal cause no harm as long as humans respect the environment we choose to live in. They are part of the ecosystem keeping things in check. Perhaps it is the hunters wanting to increase cougar kills so they will have more elk to kill?

Please let the natural system regulate itself.

Thank you for your consideration.

Subject: [EXTERNAL] Bear and Cougar increased hunt limits proposal
Date: Tuesday, July 18, 2023 1:38:53 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

On behalf of Carson Forest Watch Citizens' Group in rural Taos County, NM the following are comments regarding the proposed increase in hunt numbers for New Mexico's bear and mountain lion populations:

- 1) We have been involved in predator management and protection issues in New Mexico for over 35 years, and have attended NMDGF public meetings and submitted comments for wildlife proposals and management concerns since the late 1980's.
- 2) We remain concerned that the recent NMDGF proposed hunt quota increases have not provided the public with hard data or RECENT population surveys and habitat usage maps that would support a scientific need for such hunt increases.
- 3) On the contrary, there has been significant loss of habitat for these animals in just the past year, let alone since the last population studies and surveys were conducted. In northern New Mexico in particular, the Hermit's Peak and Calf Canyon fires, which were the largest in NM state history and burned over 350,000 acres of prime lion and bear habitat in and adjacent to the Pecos Wilderness have decimated some of the most used and critical habitat for these and other wildlife species. Much of the severely burned area in the perimeter of these fires contained some of the best bear and lion habitat in NM.
- 4) In southern NM, it's the same situation with the large fires that burned in the Gila National Forest, also providing some of the best bear and lion habitat in that part of our state.
- 5) However- we saw no mention of the impacts of these large fires, loss of habitat, data that shows how many acres were lost or degraded for bear and lion, and what population surveys have been conducted within and adjacent to these burn areas in 2022 and 2023.
- 6) Because of the tremendous loss of habitat, stress to the bear and lion populations from both the fires and lack of secure adjacent habitat, as well as likely cub and adult mortality during and after the fires- the NMDGF needs to address how the fires affected bear and lion, if studies and surveys have been conducted documenting where in the burn areas these animals are persisting and where they may have moved into other habitat, whether this habitat is suitable, the condition of this habitat, and what this year's population numbers are showing- specific to the Hermit's Peak/Calf Canyon and Gila fire areas.
- 7) More than one season of data and surveys and observations are needed after these fires before a scientific determination can be made as to how the Pecos Wilderness and Gila bear and lion populations have either recovered, declined, or changed.
- 8) It is absolutely premature and irresponsible for the NMDGF to propose any hunt limit increase until after such studies and analysis are completed.
- 9) Please address our concerns and withdraw any hunt limit increase for New Mexico's bear and lion populations until such studies are finished and we have more sound information as to the effects of these fires upon these animals.
- 10) Note that simply excluding the burn areas from the proposed hunt limits is not adequate. These animals can travel long distances, and are likely having to move to other habitats already occupied by bear and lion, and possibly suffering increased stress and mortality, and cannot sustain any increase in hunt numbers and loss of population.
- 11) We should be adding more protection for New Mexico bear and lion populations because of severe recent habitat loss, on-going drought, climate change and warming impacts, human population increase into bear and lion habitat, etc. Not less protection and further threats to these important wildlife species.

Sincerely,
Joanie Berde

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To whom it may concern:

There are 3 major entities who create profits from hunting, competing for a limited amount of business, aiming for quick immediate success:

Outfitters, Hunting Guides and Taxidermists, including meat processing.

Wealthy outfitters from out-of-state have bought up land and ranches in NM to turn them into high-end hunting ranches. Often they develop one, sell after a few years of exploitation only to buy more and again repeat the process. Unfortunately they don't care much about future wildlife populations, the impact on the land or our communities.

Local hunting guides and taxidermy businesses have

to adopt the same profit oriented practices to compete, shoot as many bears or cougars as possible to get a piece of the action. If they won't the wealthy outfitters will succeed in taking it all in a short period of time. The wealthy outfitters move on to "greener pastures" after they have eliminated the wildlife population.

Or, nowadays, the trophy bull elk are farm raised and trucked into NM to sell hunts for astronomic prices.

So far they haven't done it with bears and cougars for whatever reasons.

In order to increase quick immediate profits they claim here in northern NM are high amounts of bears and cougars. They often also claim there is a nuisance or even endangering impact on people to get NMGF to release more permits.

More permits also means more money for the State of NM and NMGF.

As long as the survival of any wildlife is determined by profit oriented entities wildlife will always lose. Bears nor cougars have a chance when hunted down by packs of hounds, being treed and then conveniently shot out of the tree.

I spent and still do much hiking on Natl. Forest and public lands.

From 2001 to 2012 I have seen 29 cougars and over 35 black bears, encountered several on my own ranch or neighboring properties.

From 2013 to 2023 I have encountered no cougar and 3 bears even though I spent equal amount of time hiking and mushroom hunting, less fishing though.

I would like to ask the NM department of GF to use the suggested period of 4 years to rather observe the bear and cougar population to see whether it will increase under current rules.

4years might also give us a better understanding what the impact of the seemingly changing climate will be. Increase in temperatures, more frequent and hotter forest fires will definitely impact prey and predators detrimentally.

Thank you for giving me the opportunity for sharing and giving input.

Best wishes -

Birgit McGaughey

Dear Decision-makers:

Bears and cougars are extremely hard to count accurately as is evidenced by ongoing, multi-year surveys. Game and Fish should adhere to strict science when calculating kill quotas to safeguard the remaining populations. Current proposals to raise the kill quotas are ill-conceived, disregard scientific methods, and ignore the ever-growing and dangerous climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel, and is certainly not what the vast majority of New Mexicans or Americans want for these fellow creatures. Please review with the utmost caution and revise over zealous quotas.

Sincerely,
Deborah Williamson, Ph.D.

Hello,

Thank you for allowing the public to comment on management of bear and cougar populations. I'm urging the commission to decrease the kill quotas on bears and cougars in New Mexico. There is no scientifically sound study of bear and cougar populations available to provide for an accurate assessment of how many bears and cougars can be safely removed from the state population without causing a significant decline in both species, a decline that would have a negative knock-on effect on those species that rely on the environmental impact of bears and cougars for their own survival. In addition, any such study would need to take into account the years of drought New Mexico has experienced and the effect of rising temperatures, which affect the food both species rely on to survive.

In closing, I once again urge the commission to consider decreasing the kill quota for bears and cougars this year and to invest in a sound, scientific study to indicate what the population of both species actually is and how climate change is affecting them. Only then can New Mexico's wildlife be effectively and productively managed.

Thank you,

Liz Johnson

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I would like to express my strong support for the proposed rule drafted by the New Mexico Department of Game and Fish biologists, which allows for the continuation of bear and cougar hunting within regulated seasons. This proposal isn't merely about sport; it's about sustainable wildlife management, maintaining a balanced ecosystem, and conserving our natural resources.

The predator hunt programs have been designed with scientific expertise and thoughtful consideration of the delicate balance that exists within our local ecosystems. By regulating the population of these predators, we can ensure that they don't become overpopulated, leading to a negative impact on other species and the overall health of our environment. I firmly believe that responsible hunting practices, guided by the professional insights of our game biologists, can contribute to the well-being of our wildlife and their habitats.

I understand that the subject of hunting can be emotionally charged for many. However, I urge the New Mexico State Game Commission to carefully consider the well-researched and scientifically sound proposal at hand. By adopting this rule, we not only respect the natural order, but we also safeguard the intricate connections between species that make our environment vibrant and robust.

Much appreciated, Jeremy Byrd

Dear New Mexico State Game Commission,

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and we support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, we believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

We respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

We as hunters fully recognize the impacts of not adhering to science based management and fully dismiss views based solely on emotion.

Respectfully,
Ethan Shoop (New Mexico resident hunter)

NM Game and Fish,

Bear and Cougar quotas drawn up by graduate students don't have proven science behind them. Increasing proposed kill quotas is short term thinking during a prolonged and deep drought with habitat and forage loss.

Your income is derived from selling hunting permits. Let the bear and cougar live. The ranchers' Wildlife Service in Grant County, NM only shoots cougars, they never relocate trouble cougars. They only shoot bear here, they never relocate as their contract states they must do first.

We are saying no to increasing the kill quotas. Thank you for considering our public comments in your decision making.

From: [Charles Barnes](#)
To: [DGF-Bear-Cougar-Rules](#)
Subject: [EXTERNAL] Bear and Cougar regulations
Date: Wednesday, August 16, 2023 11:50:57 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

To Whom It May Concern,

I am writing to express my strong support for maintaining the current rules and regulations concerning the management of bear and cougar populations in New Mexico. As stewards of our natural environment, it is essential that we strike a delicate balance between conservation efforts and public safety. The rules in place that govern these apex predators have demonstrated their effectiveness, and any alterations could potentially disrupt the equilibrium that has been established.

Bears and cougars are integral components of New Mexico's diverse ecosystems. They play critical roles in maintaining ecosystem health and biodiversity by controlling herbivore populations and influencing the structure of plant communities. Altering the current regulations could disrupt these roles, leading to unforeseen consequences such as overpopulation of prey species and habitat degradation.

Furthermore, consistent rules regarding the management of bear and cougar populations are essential for public safety. By keeping these regulations uniform, citizens can be better educated about how to coexist with these predators, thus reducing the potential for conflicts and promoting responsible outdoor behavior. This is especially important in a state like New Mexico, where outdoor recreational activities are a significant part of the culture and economy.

Maintaining the current regulations is also vital for research and data collection. These regulations have been developed based on a thorough understanding of the behavior, ecology, and population dynamics of bears and cougars. Any changes could disrupt ongoing research efforts and hinder the ability to accurately assess the impact of these predators on their ecosystems. Consistency is key for building a robust body of knowledge that guides informed decision-making.

In conclusion, I urge the New Mexico Department of Game and Fish to maintain the importance of consistent bear and cougar regulations. These rules have been carefully crafted to strike a balance between conservation and public safety, and any alterations could upset this equilibrium. By upholding the existing regulations, we can continue to protect the state's natural heritage and promote responsible interaction between humans and wildlife.

Thank you for your dedication to preserving New Mexico's unique and precious ecosystems.

Subject: [EXTERNAL] Bear and Cougar rule changes
Date: Friday, August 25, 2023 4:40:48 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Good morning, I wanted to take a moment to give my input on the proposal for the rule changes on Bear and Cougar hunting in New Mexico. I will start off by telling you a little bit about myself. My name is Tim McElheny and I live within the boundaries of unit 34 in Southern NM. I have been a houndsman for a little over 10 years now and I truly have a passion for hounds, lions, and bears. I also believe the amount of time I spend in the mountains trailing, catching, photographing, and at times harvesting these amazing animals gives me a good perspective of where we stand with populations and changes over the past 10 years. So my input would specifically be in my home unit (unit 34) and surrounding areas. My observations of this area prior to lion removal efforts for big horn sheep showed a strong presence of lions, but I would not say over populated. Most lions we caught during this period were healthy and females typically had good reproduction rates it seemed. During this time sign from these lions was difficult to find at times and I am unsure if this was due to the fact several large males covered much of this territory or if the higher populations allowed for less communications. But fast forward to today post big horn sheep lion removal. There have been significant impacts to the lion population across the unit but very specifically to the west side of the unit. Places I used to be able to get a lion started nearly everyday now seem nearly void of lions at times. This has drastically impacted the lion sign especially scratching by Tom's specifically. If there is a Tom working an area now we will typically trail and eventually catch these lions due to their consistency in marking their territory, therefore making them easier to locate and find. I believe this is due to a lack of lions using this area encouraging more communications to find other lions. My main question for this unit is why lower the quota if you are going to continue to pay a contractor to remove lions? Why not allow hunters maintain the lower Lion populations that seem to be required for these native sheep to survive. It really makes no sense to take from paying hunters to give to a paid contractor. Aside from that I currently support the cut to hopefully allow the population to recover from the big horn effects. But please consider allowing hunters to manage these numbers vs a contract hunter. Bear population seem consistent with small noticeable changes year to year based on what harvest were the previous years. I personally have a ton of respect for bear and lions and want these animals to be managed as well as possible to sustain them well into the future. I would love for my daughter, 20 years from now to have the opportunity to trail these animals through all of the beautiful country our state had to offer if she so chooses. As far as hounds I would say the larger percentage of houndsman don't do it to kill but for the love of the dogs and the ability to see new amazing places that might never be visited if it weren't for following hounds in pursuit of lions and bears. I would challenge anyone with thoughts otherwise to reach out to me and go out with myself and my hounds. I would like to see a change to the removal of bear and lion meat from the field. The meat from these animals is perfectly edible and good at that. I hate to think of these animals being wasted and I do believe this rule should change. I also stand behind the use of hunters with hounds and having the ability to discriminate on harvesting animals based on sex, age, and condition is an invaluable tool to manage populations of these animals. Hopefully my thoughts and input will be considered as you move forward into this process. I could talk about this for hours but I think this email will cover my main concerns at this time. I would be more than willing to talk to anyone interested in my view on this subject and specific area my phone number will be on this email please feel free to reach out to me now or in the future if you would like to discuss this subject more. Thank you for your time and attention.

Dear New Mexico State Game Commission,

Our North American Model of wildlife conservation and the Public Trust Doctrine define wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based wildlife management. I continue to support legal bear and cougar hunting as an appropriate management tool in the collective management tool box. Please continue to advance sound stewardship policies that are guided by science not politics, emotion and conjecture. Recent articles in the ABQ journal and NM Political Report are based purely upon emotion and offer no science backing to their statements.

The proposed changes to the bear and cougar rule are modest adjustments to the current rule which has maintained healthy and abundant populations of both species over time.

Please prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

I encourage folks to spend more time in the forest or desert and see for yourself that these species are indeed thriving. Their signs are everywhere. Observation is a powerful tool.

Sincerely,

Mike Rearick

Dear DGF,

I am a local houndsman from up in the Farmington area and I would like to send out a quick word.

Being a 3rd generation houndsman means a lot to me and also my family. My kids are a bit too young to really get out quite yet, but as soon as they get a bit older, they will be 4th generation without a doubt. I Have done a little bit of research on how these anti-hunting groups have been trying to flood us hunters out by attending some of these meeting held across the state. I don't think this is right for someone that has no clue about hunting, trying to take our traditions away. I believe I speak for all of us hunters/houndsman when I say, hunting with hounds is more than just a sport, IT IS A WAY OF LIFE...

Thank you for your time.

This email is to support Bear and Cougar hunting in New Mexico. I am an avid outdoorsman, hunter and registered guide and know the necessity of controlling predator populations.

If the anti hunting groups have their way and ban bear and cougar hunting, this can have a detrimental effect on not only the other wildlife but on humans as well.

Not only do I strongly support hunting but I also feel the harvest limits for bear and cougar need to be increased. It is very common for several zones to close within a week or two after opening. This should indicate an abundance of animals and require a higher harvest limit.

Thank you for your consideration.

Dear NM State Game Commissioners,

As an avid outdoor hiker, hunter, and fisherman, I support our American model of wildlife conservation. I support science based decisions on hunting to maintain healthy and sustainable wildlife populations.

Without hunting and fishing the American model of conservation would die, and wildlife itself will suffer the consequences.

I support the proposed rule changes to the bear and cougar hunting regulation. They will help maintain a healthy bear and cougar population and allow hunting and fishing to continue to support wildlife conservation.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

As a full time resident of northern New Mexico, I fully support bear and cougar hunting. I strongly recommend following the recommendations of wildlife biologists, who research and understand overall ecological needs best. We are long past the possibility of healthy ecosystems without hunting management. In addition, these hunts are critical cultural heritage that is part of the fabric of our state and nation. Hunting is also a way that I am able to provide for my family by harvesting healthy meat. Without a freezer full of game meat, the last few years would have been much leaner.

Thanks,
Scott Thalacker

Hello-

I am in support of these new changes. NMGF first responsibility is to the balanced population of the species it is charged with managing.

There are many these days who are opposed to any sort of predator hunting. This stance, however well intended, is misguided. First, are any of these people in direct interaction with the species they wish to "save"? Do they realize that there are healthy populations of animals due to responsible game management?

Second, you cannot squeeze the toothpaste back into the tube. The prey/predator dynamic has been irrevocably changed by humans. There is no way back, only forward with proper management, taking into consideration the population of humans who have the closest relationship with these animals, (the internet doesn't count).

Third, as seen in other States such as California and Washington, when predator hunting is banned the removal (death) of bears and mountain lions still takes place as does a secondary layer of management to monitor human/predator interactions. All of this using taxpayer money to hire people for their removal. Well intended people also contribute to the removal of bears who get habituated to humans by being fed, "a fed bear is a dead bear".

And lastly, there are MANY species that are in need of attention, funding, and behavioral change by humans. Bees, frogs, songbirds, feral horses, just to name a few. The desire to change other people's behavior for a perceived, "good cause" is as misguided as believing you do not kill anything if you are a vegan or vegetarian. Agricultural crops are killers of rabbits, hawks, voles, mice, snakes, and frogs.

Let's believe in science. Let's let the Game Department do its job.

Thank you for the work you do,
KF

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

It has come to my attention that NM is trying to reduce more and more of our legal and ethical hunting rights. These hunting rights we currently have, is one of the main reasons I retired from the military and stayed in New Mexico. Taking away these rights not only affects the ability of to ethical hunters but also affects the population of our deer and elk. I live in a very rural area and constantly finding kills of the over abundant cougars that rone the lands. Not being able to hunt these predators will decrease our other herds more rapidly. Please help in maintaining our rights to hunt and help with the maintaining of the predator species.

Thanks,
John H

Hello,

I am writing to promote hunting/regulating the predator population.

As a hunter I believe it is a privilege to be able to hunt and provide game meat for my family.

I also believe that there are times that predators (Bear, Coyote and Cougar) also need to be hunted. If left alone they will diminish our game populations and move on to our livestock and pets. Recently in Questa, NM a dog was attacked by a Cougar in the middle of the day. Here's the story.

(<https://questanews.com/residents-cautioned-following-mountain-lion-attack-in-questa/>)

The dog was able to make it, but imagine what the story would've been like, had the Cougar gone after a child or elderly person.

If managed correctly we can all get along with minor incidents. But if we don't manage predators it could be like a cancer. They will spread and eat away at everything.

Thank you NMDGF for managing the predator population. It's because of what you all do that we are able to enjoy the outdoors safely, and all the activities it has to offer.

Dear Madam or Sir;

The Department of Game and Fish should reconsider the state of the world and of our environment today. Hunting should be a tightly regulated activity if, allowed at all. It is no longer the case that we need to hunt for food. There is more than enough meat on the grocery store shelf. A head on the wall, or skin on the floor is simply a measure of pure vanity.

Please do not extend the hunting season, nor increase the quotas on the number of bears and cougars that can be shot down.

It is a new world - rethinking how we live and regard the environment can be crucial to the health of all, animal and human alike. We need the animals to assist us in restoring the balance in the natural world. Killing them off will do good whatsoever. It is long past time for us to change.

Sincerely,
Debra Stark

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I'd like to voice my opinion regarding the proposed rule changes regarding bear and cougar hunting. Responsible and controlled predator hunting is an important part of overall wildlife conservation. There has been a long history of responsible predator hunting in the state and it has never caused a problem. As a matter of fact, it can be seen by those who spend time out in the field what happens when predators are not properly regulated. Since the ban on coyote hunting contests and more recently trapping, there has been a noticeable decline in small game. I've heard a lot of talk about the lack of quail in areas that normally hold healthy populations. Anyone who spends much time in the Guadalupe mountains knows how much the deer population suffered a few years back due to too many cougars. When the predators are left uncontrolled they will wipe out the prey until they have no choice but to look elsewhere for food. At that point livestock, pets, and possibly people become the target. As a lifelong hunter and hunter education instructor, I ask that you please stand up to the so-called environmentalists that can't see the long term harm they will cause. Hunting laws and regulations are in place for a reason. Long term studies and observations guide what we do. And it's hunters like me that keep those studies funded. I think our opinion should carry some weight over that of those who sit in town and judge us based on a few law breakers or irresponsible hunters. After all, you never see a news story about the guy who followed the laws and respected the land. We 99% can not be judged based on the poor actions of 1%. Thank you for taking the time to read this and consider my opinion.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am in support of keeping tags for bears and lions. They should not be taken with a deer or elk tag. Hounds and hounds men are the best way to harvest the animals. Hounds men decide which to harvest and which to continue to reproduce and help keep a healthy population. A hunter with a deer or elk tag that can kill any bear or lion along the way, would take down the population in a heartbeat. Hounds men hunt with dogs for the challenge not the kill.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

As a Hunter and a Voter I wish to let the Game Commission know of my stand on the subject of responsible, scientific based decisions concerning controlling Bear and Cougar populations.

I am in favor of the knowledge based, Game and Fish Department using Hunting as a tool to keep in balance the needs and populations of both Bear and Cougars.

The use of dogs is also one of the means to assist in the hunting these Predators that only a few people have access to. The use of dog's by a small percentage of hunters still has to abide by all laws and Limits established by the Game Commission and Should be Allowed for the Hunting of Bears and Cougars.

Without dogs, only a few hunters will ever see a bear or cougar in their lifetime in the wild and responsible population control will be extremely difficult to manage.

Sincerely,

Dear Sir or Ma'am,

It has come to my attention that, once again, a key tool in the arsenal of the North American model of wildlife conservation is under threat from a ballot box initiative. Hound hunting for bears and mountain lions is crucial for appropriate management of the species and is THE ONLY catch and release method of hunting available. It allows hunters and state wildlife agencies to selectively harvest specific bears and lions that pose a threat to human safety and livestock as well as maintain a healthy balance within the respective populations. Hound hunting also provides valuable data to wildlife agencies and allows those agencies to make informed decisions in order to implement effective strategies for conservation.

The recovery of bears and mountain lions post 1960 is owed directly to the North American model of conservation. Tag allocations and money from hunters and anglers has allowed species decimated by overhunting in the past to recover and expand their ranges through their controlled harvest and funding of research and monitoring for wildlife agencies. Removing hound hunting for bears and lions (or their hunting outright) will simply remove a way of funding their study and conservation. Instead of hunters removing problem animals, the state will continue to do it. California banned mountain lion hunting in their state in 1972. At that time hunters were harvesting an average of 300 lions a year. Following the ban, California officials have continued to remove approximately 300 lions a year using tax payer dollars.

Banning hunting does not stop the killing of lions and bears. They still must be managed. It simply moves the privileges of hunting to the state. This is not Europe. These are not the King's animals. Hunters, and hound hunters in particular have been crucial in the management and recovery of these animals in New Mexico since 1927 for black bears and 1971 for mountain lions. They should continue to play a vital role in lion and bear conservation and not fall prey to a popularity contest.

Respectfully,
Matthew Kunz

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

First of all, I want to say that I am a hunter, my family are hunters; my children and grandchildren have been taught to respect wildlife and to always be ethical when harvesting animals. I also understand that animals such as bear and lion need to be hunted in order to maintain a balance between other animals and habitat. What I don't agree with is the hunting of these animals with dogs. Let me explain why.....not only are dogs turned out during hunting season, but they are being trained during the whole year. In order to train them they are constantly chasing bear and lion. What is the ethics in that? These animals are being chased year round and caused undo stress, especially in drought stricken years such as what we have been experiencing. I know dog owners are fighting to continue hunting with the use of their dogs, but not everyone agrees with this method. Thank you for letting me voice my concerns.

Respectfully,
Loretta Ortega

Dear New Mexico State Game Commission,

I am a longtime houndsman here in New Mexico. By listening to these comments that are trying to prevent us from running our dogs is just wrong.

People making these comments have no idea the hours we put into these dogs to catch bears and lions. This the only way you can catch and be able to harvest mature animals. There is no other way of seeing the animal age class up close and personal. I have only taken mature bears and lions over the past several years with the side of my hounds. What I think needs to happen is that the out of state houndsman need to get throw in into a draw for bear season we have these people show up from across the country and 95% of the time they will kill whatever they can catch. More often than not being immature or female bears. I would like to continue this tradition down to my sons. This is something that they have grown up on so far in their lives.

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and I support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, I believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully

Brian Rudolph

Yet again our hunting way of life is under attack. I hope our weak state government won't bend the laws to appease a few who oppose bear and lion hunting. The predators need to be controlled just like anything else. I hope that another important part of our hunting heritage isn't taken from us. The point I'm trying to make is I strongly support bear and lion hunting.

Thank you

To whom it may concern,

I as a houndsman in the state of New Mexico have taken some time to write out the importances of hound hunting for bear and lion in the state.

Hound hunting for bears is important for population management because it helps ensure a balance in the ecosystem. By carefully regulating bear populations, we can prevent overpopulation, which can lead to habitat destruction and increased human-bear conflicts. Hound hunting allows for selective harvesting, targeting specific bears that may pose a threat to humans or livestock. This helps maintain a healthy and sustainable bear population while also minimizing potential risks to communities.

Additionally, hound hunting provides valuable data for wildlife management. Through this hunting method, researchers can collect important information about bear populations, such as population size, age structure, and health. This data helps inform conservation strategies and allows for more accurate population estimates. By understanding the dynamics of bear populations, wildlife managers can make informed decisions to protect both bears and their habitats.

Overall, hound hunting for bears plays a crucial role in population management by promoting ecological balance, reducing conflicts, and providing valuable data for conservation efforts. It allows for responsible and sustainable management of bear populations, ensuring the long-term survival of these magnificent creatures.

Mountain lions,

Hound hunting for mountain lions is important for population management as it helps maintain a balance in the ecosystem. By carefully regulating mountain lion populations, we can prevent overpopulation, which can have negative impacts on both wildlife and human communities. Hound hunting allows for selective harvesting, targeting specific mountain lions that may pose a threat to livestock or human safety. This helps ensure a healthy and sustainable mountain lion population while minimizing potential conflicts.

Banning hunting of mountain lions could lead to overpopulation and associated problems. Without hunting as a population management tool, mountain lion populations could increase unchecked, leading to a strain on their prey species and potential damage to the ecosystem. Overpopulation can result in increased competition for resources, which can negatively impact other wildlife populations. It can also lead to more frequent human-wildlife conflicts, as mountain lions may encroach on human settlements in search of food.

Furthermore, hunting provides valuable data for wildlife management. Through hunting, researchers can collect important information about mountain lion populations, such as population size, age structure, and health. This data helps inform conservation strategies and allows for more accurate population estimates. By understanding the dynamics of mountain lion populations, wildlife managers can make informed decisions to protect both mountain lions and their habitats.

In summary, hound hunting for mountain lions is important for population management as it helps maintain a balanced ecosystem, reduces conflicts, and provides valuable data for conservation efforts. Banning hunting could lead to overpopulation and associated problems, impacting both wildlife and human communities. Responsible and regulated hunting plays a crucial role in ensuring the long-term survival of mountain lions while also promoting the overall health of the ecosystem.

Thanks,

Christian Marrujo

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hello, my name is Antoinette Armijo and I am writing to express deep concern over the proposed raised limits on mountain lions and bears. Not only am I strongly against raising limits, but I highly oppose the cruel method of "hunting" them down using hunting dogs. This is extremely cruel and barbaric. This is 2023, we should be way more evolved as a society and we all should know better that these beautiful, intelligent animals that we're blessed to share this state with are an important part of this ecosystem. The thought of these animals being hunted down the way that they are is totally disgusting. I cannot comprehend how any person thinks that this is ok. Do they have no respect for life whatsoever? God blessed us with these creatures to respect, protect, and preserve for future generations. I come from a family of hunters and this is not what they stand for, at all. Native Americans, the original stewards of these lands only took what they needed. There's absolutely no need or reason for this to be allowed. This should be illegal. We should turn our focus to education and preservation. These dogs are turned loose with no control whatsoever. For what? To come across families, parents, babies? When a mother or father is killed, most times the entire family does not survive. Is this what we want NM to stand for? Wasteful, unnecessary slaughter of beautiful animals that are truly misunderstood? NO!!! WE need to evolve into a civilized society and make our citizens proud of what we stand for, proud of how we protect and respect our wildlife, and a model for other states. Even a classroom full of kindergarteners could tell you that this is so very wrong on every level. It's truly heartbreaking that this is allowed at all. I wish people would take the time to educate themselves about the impacts they have on our wildlife and ecosystem. We've already done too much damage to our wildlife. They already face enough threats and challenges without us humans getting in their way - such as loss of territory, climate change, and wildfires. We should be helping them to recover. We need to make their lives easier, not slaughter innocent, defenseless animals. I'll leave this email with my two favorite quotes:

Our primary purpose on earth is to help others. And if you can't help them, at least don't hurt them

Do the best you can until you know better, then when you know better, do better

Let's be a better New Mexico. Let's represent what the majority of people want. Most of us have evolved past this cruel and evil way of thinking and living.

Thanks for your consideration,

Antoinette Armijo

To whom it may concern:

I am a lifelong sportsman In New Mexico, I would like to express my deepest concern on the Bear and Cougar issue.

I strongly feel that we as Sportsmen and Sportswomen are privileged and Honored to be able to continue to hunt Bear and Cougar with or without hounds (Dogs) in New Mexico. Hunting in itself is hard, and with Hounds (Dogs) can be an essential tool in obtaining these elusive creatures.

Anti hunting activists would not like to have their pets snagged from their porch by a Cougar, Bobcat or Bear. and neither would I, so the continued use of hunting with hounds is a very viable resource to have.

Once again I strongly approve the use of hounds (dogs) for the pursuant of Bears Bobcat and Cougar.

Thank You
A concerned Sportsmen.

As a citizen of this great state one of the things I so enjoy is our wildlife. I have lived all over this great country of ours and I think it is an absolute atrocity to just declare war on these animals. I have had the honor and privilege of seeing both species in the wild and they are considered a sacred part of the circle of life to all indigenous peoples and are to be treated with compassion and respect!

The fact that “hunters” are allowed to hunt them down with dogs and murder them is an archaic style of execution. A mindset that was brought to this country when my ancestors were butchered and slaughtered in much the way.

In my opinion, the fact that fish and game is allowed to “play God” is yet another example of government overreach!

I pray that the folks who are in a position of power in the great state of New Mexico will stand up to this lawlessness and bureaucracy and say NO the ridiculous rules they set for us in New Mexico to just randomly butcher and slaughter our bear and cougar populations without even knowing how many actually live and thrive in our state. These animals have the God Given right to live and thrive! They have their place in the world as much as any of you humans who hold positions in government.

I, a Native American of Lakota descent, implore you to PLEASE, PLEASE change these laws and protect what rightfully belongs to ALL of us to enjoy.

Please say NO to the ridiculous overreach of the fish and wildlife agencies and leave these helpless animals alone to just be.

Given the uncertainty of habitat and population estimates of both bears and cougars, the quotas for both should be reduced, not raised. Kill quotas for both species have been unjustifiably high for many years. Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time. Killing bears and cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory. Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel. The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars. NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them. Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars. Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles.

Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophy' and recreation. Ask NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

Hello, I am writing to comment on the upcoming proposed rule review cycle. I've been a New Mexico hunter for the past 11 years. The hunting, fishing, and trapping opportunities are the reason I continue to want to live in New Mexico. That being said, I don't believe my vote is worth more, because of how long I've been here, or the fact that I'm a hunter. Instead I ask that you consider my points based on their own merits, and weight them based on that. I will try to be brief.

1. Wildlife resources are a public trust. New Mexicans have right to access these public resources, regardless of some people's opinions against how we feed ourselves through ethical, responsible, and sustainable harvest of these resources. Something that has been the natural right and traditions of all human beings since the beginning of time.
2. Please continue to use science based management practices for the democratic allocation of bear and cougar resources and ignore the demands of extremist anti hunting groups based on their personal religious beliefs about eating meat, that wish to control how other people feed themselves and access natural resources that belong to all of us,.

Thank you.
Sincerely,
Adam Sapp

Bear and cougar do not have any natural predators, only humans in the form of hunting. The cougar populations in NW New Mexico seem to be abundant due to the number of kills (Buried deer) found while hiking and hunting.

Hunters help maintain a healthy population in the area.

Please don't change the rules or give in to the anti-hunting mobs.

Thank you!

This may sound way too obvious of a question to consider- but why are people allowed to hunt ANY bears and cougars when they serve an important role in balancing our ecosystems? Trophy hunting is barbaric and should never be thought of as "sport". Sport implies fair competition between individuals. What's fair about a bear or cougar being hunted down by high powered rifles with scopes on them. Let's end this barbaric practice and allow these animals to live their lives unhindered from human cruelty.

Gentlemen:

I would insist that the game commission opposes any and all attempts to limit or stop trappers / guides from using hounds when Hunting bears and cougars. As I know you are well aware that the scientific method of controlling the bear and cougar population Only benefits all other species and benefits NM's revenue through selling of hunting licenses.

Anti-hunting organizations will not stop BUT someone has to stand up to them....this is your job.

I am totally opposed to ending or even restricting all bear and cougar hunting with dogs. It has been a legal form of hunting for decades without issue. Animal activists are counting on the weakness of political leaders to ignore scientific recommendations concerning the management of all predators. Legal coyote hunting has been under attack for many years and New Mexico did ban coyote contests that were a 100% form of legal hunting. It was an emotional decision and not one that was based on any science.

That was the open door for animal activists to continue their push to end all hunting in New Mexico. They raised millions on that one. They see and smell weakness and foolishly law makes feel that there can be compromise and there is not with these people. They want to end all hunting, fishing and trapping in America.

Death by one thousand cuts is the plan here. There is no compromise with these extremists. They win no matter what they do; win or lose they raise millions of dollars for their cause. They care little about science and they care even less about ranchers and farmers losses due to predators. They have clearly demonstrated that they care little about human life too when a bear, coyote or cougar killing anyone including an infant. O well-it was the humans fault.

If they do not pick a fight then they do not raise money. They will say and do whatever it takes to raise money for their retirement, huge salaries, health insurance and nice offices. They often argue about an issue having no real idea about the facts of the cause; they just know they have been told to argue and raise money. They read from a playbook prepared by staff that is skewed or out and out lies.

I ask that New Mexico Game and Fish remember who pays the bills for them and it sure is not the animal activist. Please say a loud NO to the animal activities and their effort to eliminate another legal form of hunting in New Mexico.

Bears and cougars can self regulate their populations.

Do not allow killing of increased numbers of bears and cougars until there has been a study of their populations.

Also stop the practice of allowing dogs to chase the bear or cougar until exhaustion . What kind of decent hunter lets the dogs do the hunting and then they, the big fat hunter, rides up on their ATV and shots the exhausted bear or cougar. That is not hunting, that is shooting fish in a barrel . Give the bear and cougar a fair chance.

To NMGF,

I strongly support keeping cougar and bear hunts as appropriate measures to manage predator species in accordance with sound biology.

As a now non resident, the consideration of available hunting opportunities is something that I look at and consider hunting in different states for unique opportunities.

If bear and cougar hunts are closed the long term issues could include a crash of mule deer and sheep populations as well as reduced opportunity for youth to experience the great outdoors in a sustainable way.

There is tradition and life values entrenched in the hunting community that helps youth of today and the future develop into responsible adults who value public lands and the animals on the land.

Sincerely,

A public land hunter and conservationist.

I have one question: why harvest more animals if you don't know how many bear and cougar presently live in NM? And if you did know those numbers (I don't see them), how do you know how stable the population is?

In addition, do you know the effect our drought has had on these animals? Apex predators such as these are important to a healthy ecosystem. The number harvested should not be increased without research to show that action is sustainable for those species.

Dear New Mexico State Game Commission,

I'm writing you in support of your upcoming rule changes to bear and cougar management.

As you are already aware these animals, as is true with all wildlife, must be managed for a number of reasons. The best tried and true management tool has proven to be a science based approach in direct correlation with public hunting.

We can take a look around the country and see the devastation that's unfolding in other states that has been the outcome of mismanagement of wildlife. The reintroduction of apex predators without sound management policies, the closures of public hunting seasons such as the use of hounds and trapping, the lack of access for outdoorsmen, fish and wildlife commissions that have been influenced by outside, and uneducated, sources, etc.

Please continue to support sound, science based wildlife management going into the future.

Respectfully,

Charles Holland

Hunting bears and cougars for sport is primitive and humans should be evolving way from the practice. Not even our Native American brothers engage in this primitive practice.

I am a 62 year old native of New Mexico who grew up hunting deer, elk and turkey. I even like the idea of using primitive weapons for all game animals.

I propose that New Mexico citizens like me should be entitled to be able to view the way the most recent bear and cougar population estimates and kill quotas are derived. According to what I have read, we do not have really sound information on cougar and bear populations and I am concerned that we will be allowing larger kill quotas that their populations sustain. If there is any misinformation given in the latest Rio Grande Sierran publication on this concerning matter, I would like to know what it would be. I just am a normal person concerned about letting our bear and cougar populations get too low. Our wildlife here in our beautiful state is one of our treasures and we must do all we can not to lose the species. Thank you for listening to my concern.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Proposed bear and cougar quotas are too high.

The numbers for bears and cougars killed cannot be scientifically justified. How the quotas were determined is murky at best. No consideration has been made for rising temperatures, extreme drought, or habitat loss from catastrophic fire. Bears and cougars both evolved to be self regulating. There are not too many. But over-hunting can cause them serious harm and damage.

Please exercise your oversight to not allow this to happen.

New Mexico Department of Game and Fish Attn: Bear and Cougar Rule Amendment
P.O. Box 25112 Santa Fe, NM
87504-5112

Subject: Request to Increase Bear and Cougar Hunting Permits

Hello, my name is Alex Walechka and I am writing to respectfully request that the New Mexico Department of Game and Fish consider an increase in the number of hunting permits allocated for the Bear and Cougar hunts, as outlined in Rule 19.31.11 NMAC. I believe that such an adjustment could positively impact both wildlife management efforts and the responsible utilization of tax dollars. Recent population data reveals encouraging trends in the population health of both bears and cougars within the state. The stable and healthy population levels of these animals signify the effectiveness of the current management strategies. However, as populations grow, so do concerns regarding potential human-animal conflicts. By increasing the number of permits allocated for Bear and Cougar hunts, we can achieve a twofold objective. Firstly, it would provide responsible hunters with the opportunity to contribute to wildlife management through controlled hunting. This approach aligns with the principles of sustainable conservation and fosters a sense of stewardship among our hunting community. Secondly, by allowing hunters to engage in regulated hunts, we reduce the likelihood of an increase in human-animal conflicts. If the permits were to be decreased, there is a risk that such conflicts may rise, potentially endangering public safety and the well-being of these animals. In such a scenario, the Department might be required to allocate tax dollars for costly removal efforts. By contrast, hunters, through permit fees and associated expenses, fund the opportunity to participate in these hunts, alleviating the financial burden on taxpayers. In conclusion, I urge the Department to consider the proposal to increase the number of permits allocated for Bear and Cougar hunts. The healthy population data and potential benefits for both wildlife management and tax dollars make a compelling case for such an adjustment. I appreciate your commitment to responsible wildlife management and look forward to the positive impact that an informed decision can bring. Thank you for your time and consideration. Please feel free to reach out to me if you require any further information or have questions regarding this issue matter.

Sincerely,
Alex

Good afternoon,

I am writing in regards to rule changes for cougars and bears. In unit 2, the four corners area and many other areas of the state we are seeing a sharp increase in lion activity and growth. Just a few weeks ago a lion was trapped and relocated in Rio Rancho. I'm asking that the board bring back lion trapping on private land to manage the population and be able to fill the quota. With changing weather cycles and less moisture lion and bear encounters are increasing in urban areas, houndsman are unable to run dogs and be successful. Bear management and rules should stay the same. Thank your time.

Dear New Mexico State Game Commission,

Regarding the proposed changes to the bear and cougar rule I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists. The recommendations of the department were developed on science-based data and represent modest adjustments to the current rule that have been proven to maintain healthy and abundant populations of both species over time.

In a time where partisan politics and emotions have stifled the public discourse, science based wildlife management is one of the few areas that can transcend party lines. Bears and cougars have a special place in both hunter and anti-hunting circles alike but the truth is neither sides influence should outweigh what the science tells us.

Following the pillars of the North American Model and the Public Trust Doctrine by allowing the NMDGF to manage the stewardship of the publics fish and wildlife resources is paramount. These models are the foundation of science-based fish and wildlife management, and the populations of these animals have benefitted from the departments policies and management practices.

Bears and cougars are a sustainable and renewable resource and I support legal bear and cougar hunting as a data driven management tool. I also believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

Respectfully,

Joseph Tharpe

To whom this may concern,

Our community can not afford for the lion and bear population to get out of control. The hunters help to reduce the population of these predators in the area. If there are no hunters for these predators, they will become over populated which will result in excessive killing of livestock, and pets and maybe even children. Please reconsider this information before banning the predator control as this is a life or death problem. Please also consider bringing back trapping on public land. The varmints are out of control. Thank you,

Sincerely a New Mexico resident,

You have to have predator management. A cougar will eat one elk or deer every 9 to 12 days. If you let that number multiply you will decimate our deer and elk herds. Activists don't think like that. Game management isn't a concept to them. Numerous studies show black bear are the number 1 predator to elk calves in a multitude of different environments. Keep predator management up!!! It is your responsibility to manage predators.

I am opposed to the proposed policy of killing 25% of the bears and cougars in the state. Bears and cougars are both native to NM. There is no evidence that these populations need to be managed by killing them. The population of these animals has not been established. How can they suddenly decide that they want to kill off 25% of the populations when they don't know how many animals exist here.
I

It seems to me that the Dept is actually conducting a canned hunt. They are charging people to kill our animals. The Dept of Game and Fish should be run as a humane department which treats our wildlife in a humane and compassionate way.

Good morning,

I am writing in regards to the proposed rule changes for bear and cougar.

Concerning the bear changes please follow all scientific evidence for what is best for the animal. However, I strongly disagree with changing the start dates from Sept 1st to Aug 16th in BMZ 12 and 13. Historically those units opened in Aug and the units generally closed very quickly, before the start of bow season. Leaving the dates to Sept 1st will encourage bow hunters to purchase a tag creating more revenue for the department. I know that I purchase a bear tag when I'm lucky enough to get an archery tag in those units, however I won't if the dates return to Aug as the likelihood of the unit being open is slim to none. The bow hunters are very unlikely to close the unit due to harvest, allowing the hounds men to come in the end of September and run their dogs in cooler weather.

Again please leave these two units start date as Sept 1st. Thank you for your consideration.

Dear friends at the Department of Game and Fish:

I am a lifelong resident of New Mexico, I am 66. I am opposed to raising trophy hunting quotas for bears and cougars in NM. The estimates of the population numbers for these animals is insufficient and at best, a guess. They are already stressed with diminishing territory and climate change issues. They are a part of the wildlife balance that we must continue to work to maintain.

The methods employed by the trophy hunters including the use of radio collared dogs for tracking, give the bears and cougars few options if any, for escape. The method is deplorable. It certainly is something I don't brag about when I talk with out-of-staters.

I commend your progress in halting foot-hold trapping, a decision that was long overdue. Thank you.

It is time for Fish and Game to speak loudly in support of protecting wild animal populations. Raising quotas on bears and cougars is simply uncalled for in insuring the safety of these magnificent animals.

Sincerely,
Tim Johnson

Without the ability to hunt bears and cougars with hounds we lose the most selective way of harvest of these animals, as well as the most effective conservation tool in monitoring the health of the population of these animals, with the limited resources of the New Mexico Department of Game and Fish to effectively manage populations in rough and rugged isolated environments , harvest reports play a huge role in conservation of funds and species. It also mitigates confrontation between these species and humans.

To whom it may concern

My name is Justin Lee, I would like to state my opinion in regards to the NMGFD bear and cougar hunting rules change. In the last 3 years of living in this state and spending the majority of my free time out on public lands, both Forest Service and BLM , I have had many encounters with Bears. I have observed at least 3-4 bears during hunting season every year, and have had harvest opportunities every year, though I have only taken one. I do not believe that we are over populated or the bear population is struggling. I believe that current population management strategies are working well both in providing opportunities to citizens for hunting and viewing, as well as sustaining a healthy overall population in the state.

Lions however are a different story. I do not personally hunt lions but the guys I know who do are having more opportunities every year. Lions being strictly carnivorous have a much higher impact on ungulate populations in this state and it is observable that our deer, sheep and ibex populations are being impacted by the increasing numbers of lions on the landscape. All carnivores in this state are in need of higher harvest, cougars are definitely part of this group. Hunters are deeply invested in sustainable harvest and balanced systems within this state. Trapping should be allowed on public lands, hounds should continue to be used as it is the most effective method of harvest as well as other traditional methods of take.

As a citizen of this state it makes perfect sense that hunters who contribute to wildlife conservation both in actions and financially should be used for management in a proactive management plan, as apposed to State money being used to pay contractors to depredate problem predators on a reactive basis. Let's be the example of balanced conservation for other states to emulate instead of the emotionally charged wildlife disaster that has become the trademark of our west coast states CA, OR, and WA.

Respectfully
J. Lee

To whom it may concern,

Propose to add a springer bear season statewide. I live in the northeast part of the state and number of bears I capture on game camera and see while out in the woods has greatly increased. I had 11 different bears on my cameras last year just in one small canyon. Also allow trapping of cougars .

Thank you for allowing my input.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering the state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

Dear New Mexico State Game Commission,

The North American Model and the Public Trust Doctrine define fish and wildlife resources as the property of the people, to be managed by state and federal wildlife agencies entrusted with their stewardship. This model is the foundation of science-based fish and wildlife management, and we support legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, we believe you will advance sound stewardship policies that are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

We respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures.

Respectfully,

Jonathan McKinney

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I have been hunting in the NM mountains and deserts for 45 years. The need for sound scientific predator management in NM over emotional non scientific management couldn't be more important. The fact that each year more and more people are entering our NM forests and deserts requires the NMG&F to be very responsible and diligent when it comes to predator control. Hunters, fisherman, backpackers, day hikers and cyclists should all want the NMDG&F to have a scientific approach to predator management since this approach will be the best way to keep predators in check and to maintain a healthy and robust population of predators, last but not least, to help keep the public who do not hunt safer.

I'm a hunter and I know first hand the need for predator control, in the last 4 years I have been stalked by a mountain lion and a bear, both wanted to take me out but I was able to deal with it, unfortunately many people who visit our forests and deserts do not. Without sound scientific predator management and because of the influx of people to our state there will no doubt be more and more incidents like what happened to me.

Thank you for your time and support on this issue,

John Pearce

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Anti hunters should not be taken seriously in the state of NM. For one anti hunters do not understand conservation and the love a hunter has for the land and the resources. They believe they are supporting the feelings of the animals and put the animals health and habitat at risk fighting for something they don't understand.

Although I do not hunt bear, nor cougar, and would never hunt them with dogs, I do not feel they should be supported because they will take the win as a boost to push for more anti hunting reform and will eventually create strain and non predators, big game, and habitats.

Please vote to not change the rules in support of anti hunters.

We need to keep the bear and cougar huning in New Mexico. It dates all the way back to Ben Lilly and the Lee Brothers on the blue. People make a living doing this and also peope do it because of the traditions. If we don't have the huning of these animals than the population is going to shoot up and they will be in the middle of people's back yards. So as a houndsman and fellow houndsmens we need to stick together and try to keep the huning around for the generation comming up and the population control. Keep the hounds keep the traditions.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Please continue to manage predator populations based on scientific data and not based on feelings of people that don't participate in wildlife management. Hunters contribute thousands of dollars individually to hunt elk, deer and other wildlife and further restrictions on predator management would further decrease mule deer numbers that are not near what they were 30 years ago. Hunting with hounds is a tradition that has survived for hundreds of years because it is effective, requires great physical stamina and takes years to string together a good string of valuable hounds that are bred and live to hunt.

Please don't turn New Mexico into California.

Bears and lions need to be properly managed and that includes hunting. Responsible conservation is the best way to control populations. Please resist efforts by anti-hunters who know little about wildlife conservation to dictate species management in New Mexico.

You should keep tag numbers where they are - otherwise bears and lions will die from overpopulation and starvation - but I guess some anti-hunters believe that is progress as long as they feel good about themselves.

Hello

In 2017 I volunteered to help the USDA-aphis division on the western slope of Colorado on a neonate study.

The study started in 2015, and was a study on new born fawns.

Colorado's deer population is 1/3 of what it should be, and they were trying to figure out why. After 2 years of collaring and tracking their fawns, they discovered they were losing 27% of their fawn population to bears, 17% to lions and another 11% to other predators.

I also helped manage bears in the corn and onion fields in Delta Colorado, that year alone Colorado game and fish removed 47 bears out of Delta alone.

We also removed bears in Durango that were hazing and attacking homeless people in Durango, and removed a lion that attacked a child in Mesa Verde National Park.

Colorado doesn't allow bear hunting with hounds, so game and fish removed over 700 bears in 2017 alone that were causing problems in some form or another.

Bear and lion hunting not only manages numbers in a safe and humanely manner, it brings revenue to the state in all different forms.

For example, I employ 6 guides 8 months out of the year, that buy gas, and ice in order to be able to guide hunters.

The hunters are buying hunting licenses, gas, food, hotel rooms, groceries and other necessities that are needed while they are here.

All that means revenue for the state that is much needed.

That doesn't include the 3% of my gross I pay to the forest service and another 3% to the BLM, plus self employment taxes and business license.

We can also talk about all the revenue lost due to depredation on cattle, sheep and horses if we don't keep the lion and bear numbers in check.

The Lion and bear population is at a healthy number and maybe even to high. Lion zone 1 quota is met normally by the middle of December.

That tells me the lion population is very healthy and could stand for the quota to be raised.

The bear population is very good as well.

The Gila ranchers are struggling to survive due to calf depredation due to bears and wolves.

If the state bans bear and lion hunting it will cripple the states already struggling economy, the deer and elk population will be in danger, people hiking and biking will in danger and the already struggling ranchers will be out of business.

I encourage everyone to look up the neonate study to fact check all my statistics.

Dear game commission, the August Bear seasons should be reinstated for the Los Alamos zone. We have way too many bears in this town. The quotas should also be raised. Our quota is usually met by mid October. Also the cougar quota needs to be raised as well. Do not remove the use of dogs and a hunting method. The use of hounds is the only good way to properly judge age and sex on these large predators as to limit take of female and adolescent animals.

Thanks,
Peter Walker

You need to raise the quotas on bears and lion. There are to many bear and lions in 6c. We have bears all over Los Alamos and the lions have moved in too. Several dogs and goats have been killed by lions in Los Alamos in the last year. We need the August bear hunt to be reinstated in this unit as well. Being able to pursue these large predators with dogs is a crucial management tool to keep these predators in check. Do not make use of dogs an illegal method of take.

Thanks
Peter A Walker

Dear new mexico state game commission I believe that the way bear hunting is regulated right now is absolutely working and is going the way it should be so It should be left alone. I believe the same for mountain lions as well. I think moving hunt start dates for bear back to August would disrupt pre rut elk and other species before archery season would start which leads to alot more problems. Thank you very much but I believe bear and mountain lion hunting should stay the same and we should focus on another subject as a state like bringing trapping and coyote contests back.

Hello,

Being Californian but living here for 10 years have taught me that it is never a good idea to bring the politics of my home state to New Mexico. One of the reasons I left California is the same reason other people want to impose those same laws and restrictions. Being a new hunter I've learned how important my role is to depredation hunting and population management. Where if left unchecked will cause more harm to the people in Raton and other rural towns all over the state

Hello,

The bear and predator management needs a reboot. Seeing predators should be RARE. Anymore, you see more predators on a game species hunt than the game species. It's hard enough to draw hunts let alone competing with predators.

1.) I propose allowing the game limits be met regardless of it being a female or not. The zones close within hours of being open anyway because females get hit on the road.. and those count toward the mortality limit..so not only does the hunt close prematurely.. but all the other females are having 2-3 cubs. The population in a 5 year span gets blown out of proportion.

2.) Allow hunters to harvest a predator on a drawn hunt before getting a tag but the tag must be purchased within 24 hours of the kill and inspected.

Or... sell the predator tags at a discount with a fishing license... something along those lines.

Ps don't you dare introduce grizzlies back into NM. OR JAGUARS. Or Canadian grays.

Thank you,

Landon Ryan

Dear sir or madam

I believe in and support hunting of bear and lion in New Mexico. I live in a rural area of sw nm and have continuous run ins with both bear and lions. I have lost numerous cattle and a horse over the Years and firmly believe that hunting is the only way to keep the numbers down, which in recent Years the numbers in my area are going up steadily. They are becoming more aggressive and care less about humans.

Please keep our hunting of lions and bears as they are and let us protect out livelihoods.

Thank you

Preston johnson

Hi this is a very concerning matter. Our predator problem has increased in suburban areas and it would be very smart to leave this matter in the hands of the game and fish department. Hounds does indeed give us an advantage. However is it a MUCH NEEDED advantage to keep our big game, and small game numbers thriving. If we want to keep New Mexico a state of the art area to hunt big game. It would be in our best interest to keep the use of hounds legal.

Every year the Department of Game and Fish comes up with how wildlife numbers have increased and the wildlife needs to be exterminated.

It always seems that rather than protect our wildlife the department favors allowing hunters to kill our wildlife.

How often has anyone seen a bear, cougar, deer, coyote, even a rabbit, squirrel or chipmunk when enjoying our open spaces, fields, mountains, lakes etc.

There aren't even birds in the numbers there were once. It's a pretty dismal statement of how we value our wildlife and open spaces.

I am asking that the department NOT increase the number of bears, cougars or any other wildlife to be killed so that we and future generations can enjoy them.

Thank you,

Ruth Connery

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am a life long hunter and fully understand the need to carefully control both predator and prey populations. However, this rule seems to lack a sophisticated assessment of the real state-wide implications of increasing the quotas on cougar and bear. In particular, it appears not to take into account that such a proposal in the midst of ongoing drought and severe fire damage entails a high degree of scientific uncertainty about the impact on the affected species and the biome. Moreover, there appear to be some extrapolations on state wide numbers based on limited data from limited geographical areas. This is too important a task to proceed with such lacunae and requires a comprehensive data collection if it is to be a credible and appropriate approach.

This proposal needs much more work before being finalized and I hope that the New Mexico Game and Fish Dept will certainly not increase the quotas from their current levels until it conducts such an analysis. Moving forward without better scientific certainty about the implications of this proposed rule would be a mistake. Thank you for considering my comments.

This is Don Fell from Silver City ,the bear and cougar seasons need to stay in place,as they are,to help to control these predators, When you change or take away from a hunt all you do is increase population wheather it be bear or cougar , The number of bears allowed to to be taken seems high ,but anymore not very many hunt them like they used to in the earlier days, seems tjough that the qutas arfre met ,sometimes early comes last up to the last day of a season.If you put a quota on females such as 100 and you look at how many cubs a female have during the birthing period then you have kept it in check for the amount of females there are Just a example}.do away with it and come time for cubs, say she has three (rare) then the next year she has two thats five added to the population in two years, How many bears in New Mexico?? same with cougars they usually have three the ones i have seen over the years have three kittens, no hunting of cougars, in five years she has had 15 added to the population,then more elk calfs killed, more deer fawns taken out just from cougars and bears will take down elk little ones, same with a deer fawn ,Conservation includes trying to keep numbers in check,so you do not have a complete wipe out of other animals say in ten years, then you have more staliking people when food is short , and more in town sightings need to keep as is .I have a tag for each have seen them but never have tagged one, but to me after a lifetime of hunting i still hope the money i spent is put to good use, and there are alot of differant numbers between Northern New Mexico and Southern New Mexico for both. IN THE END NOT THAT MANY BEARS OR COUGARS ARE BEING TAKEN. .

My name is William M. Varos and me and my family are avid outdoors enthusiasts. Both my wife and I have degrees in wildlife life biology from Texas A&M. So when I say that not managing the predators (bears and cougars) is part of a management program that benefits all species, Not to mention the increased loss of livestock and game animals that will inevitably occur. Why can't we learn from states such as California where attacks on people increased. Oh ya don't forget about the revenue that will be lost that is used for all wildlife conservation efforts.

Billy Varos.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I am appalled that in this time of wildlife extinction, you are considering upping the amount of killing allowed of bears and cougars. There is entirely too much leeway given now to hunters and trophy hunters and it needs to be curtailed. My reasons for this include:

- Given the uncertainty of habitat and population estimates of both bears and cougars, the **quotas for both should be reduced**, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can and will impact their populations for a long time.
- Look at history and the senseless slaughter that people engaged in that wiped out whole populations of wildlife.
- Thank you for your time,
- Susan Roberts

Please dont allow the antis to take control of scientific game managment. The need for hound hunting is real.

Colorado allowed them to take spring bear, bait and hounds at the ballot box and bears have become a real nuisance and danger to rural home owners and campers alike. Hell theyre a problem in town n cities as well. Raiding dumpsters and trash receptacles is far to common along with Attacking pets and livestock. Dont turn your wildlife agency into a tax payer funded killing organization. Generate income to protect and manage ALL game n wildlife through liscense sales, outfitter permits, etc.

Thank you,
Ole babcock

Hello, to whom it may concern.

My name is Andrew McWilliams, I am an Outfitter here in NM. I believe in conservation and management of wildlife here in NM.

I support the change of dates for gmu 34 and 36 back to the way it used to be with opening dates of Aug 16th for Bear season. I believe that it will be beneficial to healthy sustainable bear populations in the units, since bear hunters/ hounds men will be spread though out several units.

Please consider making this change as I believe it will allow hunters more opportunity as well as reducing stress on game and over harvesting in any given unit at one time. Allowing future generations healthy Bear Populations though out New Mexico. Thank you.

Respectfully,

Andrew McWilliams/ Wildspirit Outfitters

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Good afternoon, I am reaching out today to request GMU 36 and GMU 34 August bear hunts to be put back in place.

Below are my reasons:

- I have personally reached out to every houndsman I know in Lincoln County and each one agreed they would like to see this happen. I spoke to at least 6 houndsmen. As a resident of Ruidoso (GMU 36) I can tell you there are plenty of bears around. I usually see at least one in town every year. I think opening this hunt back up will help with bears in town.
- The pressure of bear hunters/houndsmen in GMU 37 (Capitan Mtns) is overwhelming in August. This is the ONLY open GMU in the entire Southeast Area for bears in August. It creates a cluster of hunters in one area and is not fair to our bear hunters.
- As you know or can see, the quotas of bears being killed in 34 and 36 is usually met or close to being met each year. We have no shortage of bears and I believe this would create more opportunities to hunt.
- The weather in August in 34 and 36 is actually cooler than 37 (Capitan Mtns). This would mean hounds would be fine running this time of year.
- There is also no data to show that the closer of these units has benefited and animal population or outdoorsmen in anyway. As you can see there is more data or at least interest in opening these hunts than there is against it.

I ask you hear the voices of your local Hunters and help us get this goal accomplished for the coming rule cycle.

Thank you!

I would like to show support to reopen the Aug 16-31 bear season in the southern units. They were taken away without good reason.

For many of us bear hunters this is the only time that we get to be in the woods without sharing it with other hunters. It has also caused more pressure in other areas because the hunters that live in the south now have to travel and hunt other areas that they normally wouldn't.

August is a great time for family's to bear hunt and continue on our traditions of hound hunting.

Many outfitters depend on this time of year to take hunters that did not draw at tag but still want to hunt.

Bear, and cougar need to be managed like all other wildlife. If the biologist see that there is a surplus of a given species, or that food conditions are not sufficient to maintain the the current population, there needs to be a hunt.

Trying to set one or two species away from normal practices is nothing but a ploy by people who want to see all hunting done away with, and do it one or two species at a time. As I understand it there is a group that want to end seasons on the above species. Are you going to limit normal wildlife biology, and game management practices to all except bears, and cougars?. Those animal **MUST** be managed the way all game is managed, not set aside to quiet a vocal minority.

Wildlife management is a science that should be applied to **ALL** game animals. There is no room to make exception for certain animals, and pretend they should be managed differently, or not at all.

The people who make these requests want to end all hunting, and for that matter they would like to make it illegal to eat meat. Bears, and cougars are their subject for the day, next time it will be something else in their quest to end hunting one, or two species at a time.

They did something like this in California, and the cougars started attacking joggers. Thank you for your time.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

I am strongly opposed to and horrified by the Bear and Cougar Trophy Hunting Rules proposed by the NM Department of Game and Fish for the next four years.

These rules are largely not grounded in science and should be reduced by at least 50% given the overkill in previous years due to use of non-existent or flawed science in establishing quotas. In addition, NMDGF proposes to only count legal kills by hunters towards their kill limits, instead of all sources of bear and cougar mortality. Total mortality includes disease, predator-control kills, human conflict kills, road-killed wildlife, and the significant amount of annual poaching. Clearly, NMDGF is taking an easy and ill-informed approach by not taking any of these other causes of mortality into account. NM's cougars, bears and residents who value these precious animals deserve much better from NMDGF.

The Southwest has been experiencing a "megadrought" from 2000-2023. As a result, New Mexico also experienced the most severe wildfires in recent history, destroying habitats, food and wildlife. NMDGF has failed to account for these factors in its habitat or population estimates. Climate trends weigh strongly in favor of lowering kill limits, not increasing them.

New Mexico's bears and cougars are an essential part of a healthy eco-system for all inhabitants of this state. I am horrified at the prospect of increased kill quotas for the benefit of trophy hunters. The American public opposes trophy hunting by 2/3rds majority. NMDGF should consider this broad public opinion, adopt hunting rules that ban the use of dogs in cougar and bear hunting, reduce the proposed hunting kill limits by 50%, and include all human-caused sources of mortality in the kill limits. It is way past time for NMDGF to do the right by our bears, cougars, and environment. Clearly, they are of much greater value than fees from trophy hunters, and NMDGF needs to finally recognize this and respond accordingly, by reducing the proposed kill limits.

Date: Thursday, August 24, 2023 12:37:11 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hello New Mexico Department of Game and Fish & Commissioners,

Thank you for this opportunity to speak my thoughts about increasing quotas and extending hunting seasons for Bears and Cougars.

The idea of putting more pressure on both species, particularly females, in this every growing drought (last year alone, 2 fires consumed 666,800 acres of primary wildlife homes and range), which impacts forage and negatively impacts female bears denning sites and slow reproduction rates and losing preferred home ranges makes the idea of increasing quotas a scary proposition. Cougars, particularly mature males, when hunted and killed disrupts the social hierarchy of younger dispersing males, preventing them from learning the boundaries and rules which are established by fully adult males living in their established territories.

According to many scientists your estimated numbers state-wide are inflated population estimates.

How can you justify hounds to chase cougars and bears in the hot weather, particularly bears, who's coats are dense and in a chase they will over heat, and, they are not good climbers anyway, it is just a blood sport and abusive to our wildlife.

Bears and Mtn. Lions are iconic species of New Mexico & in the Southwest, and in the Zuni culture a they are glorified in fetish carvings and their ancient traditions.

Please do not increase your quotas and take a good hard look at what challenging times our wildlife are experiencing.

Thank you for taking the time to read my concerns,

Dear NM Game and Fish Commission

We are very concerned about the plans for bears and cougars aired by NMG&F.

The health of territories depends on biodiversity; animals must be represented in certain numbers, not as just a selected presence. Due to these principles, we suggest

- NMDGF's proposed trophy hunting kill limits for bears and cougars should be reduced by at least 50%. The kill limits are not demonstrably sustainable and have little basis in sound science.
- Trophy hunt must be banned..
- We're afraid that the Commission is not considering that biologists have conducted few scientific studies of New Mexico's bears and cougars, so that the empirical data is limited. Old wisdom states that fools rush to go where angels fear to show, meaning not to act unless scientific data allow us to.
- In the case of black bears, NMDGF uses mostly outdated studies conducted in the best bear habitats and then generalizes the results statewide.
- And in the case of cougars, NMDGF relies on an old, flawed habitat model to set kill limits for the majority of cougar management zones, despite more recent and reliable studies demonstrating that this model produces inaccurately high population estimates.
- NMDGF's kill limits are largely not grounded in sound science and should be reduced by half at least.
- Thank you
- Marina Sagardua
- Boston ,MA

Department of Game and Fish.

I understand bear and cougar rules are open for change this year. I am a rancher in north eastern NM. I have seen more bear and cougar activity over the last year than I did from 1964 to 2000 combined. Both bear and cougar predation significantly affect my ranching operation. I strongly urge you not to do anything that might decrease the take of bears and cougars in any way.

Thank you

Good morning,

Comments

Open more units for 1st season bear with more and more out of state dog hunters flooding in every year it's making it difficult for us resident hunters & outfitters to hunt our own backyard.

Reduce OTC lion/bear tags to non residents houndsman utilizing dogs.

Thanks

I know that hunting is the greatest conservation tool we have to regulate populations of animals, most non hunters do not understand how much hunters put into the conservation efforts in our state, after viewing the proposed changes to the bear/cougar rules I think they are a great idea!!!! This shows how are efforts are increasing the population of both species, and having the biological data to show that, is fantastic!!!!

To whom it may concern;

As an avid hunter, fisherman, and outdoorsman, I am reaching out today in support of proposed changes to the New Mexico Game and Fish, Bear and Cougar management policies. Some of my most memorable moments in the outdoors over the years have been my close encounters with black bears. I have had several unforgettable encounters with them while bow hunting elk in the San Mateo Mts. They are truly amazing animals and I love to observe their antics and behaviors. Most of my encounters have been benign, but I had a very close call back in 2017 with a big boar that wanted to claim a bull elk I had harvested with my bow and arrow, so I know first hand how aggressive they can be. The biologists and researchers who work diligently to collect accurate population data on Bear and Cougar populations within our state to ensure sustainable, healthy populations of our large predators should be commended for their work. So often, their expertise and advice is undermined, ignored, and overlooked by groups who do not support the hunting sports whom argue against predator hunting based on emotion and feelings instead of hard science. Unfortunately, these groups have been able to use the legislative process to push their agendas through because they have a louder voice, deep pockets, and better organization.

As a human, I love to observe predators in their natural habitat. As a hunter, I want to continue to share the woods with them and do my part in keeping their populations at a healthy level through ethical hunting practices that are carefully regulated and monitored by our Game and Fish experts.

The only way I can ensure that my grandchildren have the opportunities I have had to enjoy the rich tradition that is the North American hunting experience, is to stay vigilant and support legislation that protects my rights as a hunter. Please consider that my thoughts and my opinions are shared by countless others within this state, (a silent majority if you will), who either don't take the time to address you, do not know how to address you, or simply may not be informed.

Sincerely,
Joel Gothard

Good evening. I just wanted to voice my opinion on the 2024-2028 New Mexico Bear and Cougar rule changes. I support the research that is being done to manage populations and habitat of bear and Cougar. I've personally seen game wardens and biologists doing exactly what is supposed to be done to ensure the most quality research and management. Therefore, I FULLY support their decisions on the changes.

I am from West Virginia but my husband and I spend a small fortune in your state every year coming to hunt bear and cougar with our hounds, and we stay absolutely as long as we are able. New Mexico is by far our favorite place to hunt and we hunt essentially coast to coast every year.

Rick Winslow, bear biologist, has been an incredible help from the first time we started hunting in NM. We've met several game wardens, Ariel Perraglio, Kirt Defenbaugh, Kayla Brauer, to name a few, who have been so professional, knowledgeable, and supportive. We fully support the NMDGF and are looking forward to being back in just a few weeks!

Dear Game Commission,

With regards to proposals to eliminate or greatly restrict bear and cougar hunting in New Mexico, I must express my opposition to any such changes to existing game laws in New Mexico. Big game, to include predators, must be managed with science and not emotion. I fully support the continuation of current hunt strategies for bear and cougar in New Mexico. The New Mexico Department of Game and Fish is fully capable of prescribing hunt strategies to manage bear and cougar, to maintain sustainable and healthy populations of these game animals into the future. Thank you for your consideration.

Respectfully,
Jeff Rivera

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban. The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences. California is the perfect example. One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

To Whom It May Concern,

How are you doing?

I would like to express my deep concern with the potential loss of bear and cougar hunting with hounds in New Mexico. The use of hounds has deep cultural and ecological importance. The use of dogs to pursue game goes back many centuries and taking this opportunity away not only destroys generational knowledge and education but also creates a loss of identity for many men, women, and children who love the sport. It is a way of life.

Something that many people overlook is the ecological importance and ability to use very selective harvest when hunting with hounds. Having the opportunity to really evaluate an animal while treed or cornered allows the hunter and hounds man to be selective in their harvest. By selective, I mean it the hunter or hounds man can take the time to look at the animal and determine the sex and maturity so that mature animals are harvested and no females with young are killed.

I urge you to protect this sport, this ecological management tool, and many people's way of life.

If you have any follow up questions and concern please follow up with an email.

Best,

Jace Cussins

Date: Friday, July 21, 2023 9:37:54 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

- Given the uncertainty of habitat and population estimates of both bears and cougars, the **quotas for both should be reduced**, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.
- Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.
- Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.
- The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the

public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

- NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.
- Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.
- Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophies' and recreation. Ask NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

Hunting rules/laws should be written by Hunters for Hunters. Too many people who make the rules/laws are writing them due to sentimentality or ignorance. Most hunters do so to put meat on the table or monies in their pockets to buy food, etc for their families. Another example is no Doe hunts. This should be an option in the draw (another issue..) New Mexico is overrun with does who are weak and dropping weak fawns due to the bucks being younger and attempting to cover 150 does each.

Dear Commission,

The North American Model defines fish and wildlife resources as the property of the people, to be managed by wildlife agencies on behalf of the people. This model is the foundation of SCIENCE-BASED fish and wildlife management, and I encourage legal bear and cougar hunting as an appropriate management tool. As caretakers of this trust, I believe you will advance sound stewardship policies that represent New Mexican traditions and are guided by science over politics, emotion and conjecture.

The proposed changes to the bear and cougar rule represent modest adjustments to the current rule which has been proven to maintain healthy and abundant populations of both species over time.

I respectfully request that the State Game Commission prioritize the opinions of our dedicated department biologists and the recommendations developed from their science-based data such as non-invasive scat or hair sampling, remote/trail cameras, GPS collars, and other traditional measures. Please avoid letting emotions guide your policy making and continue to keep New Mexico at the top of the list as an example of sound and balanced land use.

Sincerely,

Stephen Puntch

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I'm 73 years old and grew up in a fishing, hunting, trapping family. It was a way of life for us, and my grandfather impressed upon us that you eat what you kill. I have eaten squirrel, rabbit, dove, quail, turtle, possum, rattlesnake, deer, bison, and the beef, pork, and chicken we raised and processed on his farm.

Over the past 30 years I have read a lot about habitat loss, climate change, and the extinction crisis. My wife and I began turning our property into a mini nature preserve, planting native pollinator plants and trees, as well as water features for frogs and birds.

I have always admired Fish and Wildlife Services, and bought my share of hunting and fishing licenses. I decided to attend the Las Cruces meeting on bear and cougar management proposals. I read the proposed plan and was surprised to learn that the NMFW used the term 'harvest' to describe the proposed slaughter of New Mexico's bears and cougars because of a model that determined how many could be slaughtered without affecting the population.

I was struck by the number of times the word harvest was used, referring to the number of bears and cougars which are considered keystone species, could be slaughtered. It was pretty shocking, and I began to realize how naive I had been to actually believe the mission statement of NMFW. As the presentation continued, I realized that these animals, which create opportunities for other species to survive and thrive, were simply a commodity to be auctioned off to the highest bidder, who is willing to pay for the joy of killing an animal that has lost over 50 percent of its original habitat in the last 100 years, is being threatened by wildfires, climate change, vehicle mortality, poaching, and the notorious Wildlife Services.

In the face of all this, NMFW continues to do the same thing it has done for years, the classic definition of insanity.

I continue to believe that most of the people working for NMFW started working there because of their love of the outdoors and nature itself, and a desire to make a difference for wildlife. Maybe it's time to rethink everything the department stands for in the face of all the challenges we're facing. I think we can and must do better than this.

Sincerely,
David Patterson

Rules for game management should be based on best science and sustainability for population management, not feelings or how it fits into an agenda. Therefore I am against any rule that would curtail the legal hunting or seasons for bear or cougar in New Mexico. To do so endangers the stability of the populations, increases the likelihood of animal/human confrontation and negates a revenue source that is needed to manage and maintain the viability of the populations. A ban on hunting these species should not be considered by this commission.

It seems preposterous to me that any ban on hound hunting even be considered. There is a balance that must be maintained among all animals. Hounds provide the ultimate way to take what needs taking and release what needs releasing. Furthermore, hunting in general brings incredible revenue to areas that otherwise doesn't have it. Regulations should of course be in place, but a ban on something that provides for families both involved with hunting and not involved is something that should never happen.

We attended your meeting a few months ago in Albuquerque, regarding the "Bear/Cougar Rule." Proposal.

Most people attending did not support your Rule, which unfortunately reflects the antiquated, out-of-touch ideas on "management of wildlife." Hunting and Trapping of wild animals appears to be your main objective.

Those who truly care about the future of wild animals will continue to monitor your proposals, and speak/act accordingly. We do not remember any discussions on Climate Change in N.M., at this meeting which leaves many of us to doubt your ability to "manage:" wildlife issues in the coming decade, let alone, sooner.

Climate Change is already upon New Mexico, and it will have far-reaching ramifications for wild animals, their dwindling habitat-- and their survival. Game Depts. which continue to remain mired in old management scenarios will not be relevant, and will be a further detriment to wild animals' survival in New Mexico's changing climate: This is why the whole idea of "wildlife management" will have to change to philosophy of Preservation instead of Management.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Born and raised in California, and now residing in Colorado, I have now lived in two of the most mismanaged predator states in the country. California in particular as an out of control lion and black bear population, and this is one of the main factors in a deer population that has tanked for decades. Not only is it bad for ungulate populations/contributing to unbalanced ecosystems, it takes away experiences and livelihoods from sportsman, and demonizes these awesome creatures. A booming population of predators leads to a decline in ungulates, and leads to more direct human-predator conflicts, both of which cast predators in a negative light, and widen the rift between the public and the misunderstood animals.

As a wildlife/fisheries biologist myself, it pains me to see what has happened to a lot of the natural resources and hunting culture/public perception in my home state, and some of these same policies are starting to take hold of Colorado. I do a lot of work these days in New Mexico, and it would be a shame to see the trend continue down there. Please let the professionals and science be in charge of managing the wildlife, and not the general public whose entire outdoor lifestyle generally consists of couple small park hikes a year, and will likely never even get close to actually seeing a mountain lion or bear.

Please protect these resources, people's livelihoods and cultures, and help prevent worsening the public image of these predators.

Thank you.

-Chase Higgs

Chairman Lopez and members of the State Game Commission,

I want to add my voice to those who support wildlife management that is based on science rather than political pressure, conjecture and emotion. I urge you to approve the proposed Bear/Cougar Rule as written for the 2024-28 cycle.

Having followed the bear/cougar debates for numerous four-year cycles, I don't think the underlying science has changed. NMDGF has consistently managed both populations in a way that has kept bears and cougars at healthy numbers. Over the years biologists have honed their statistical modeling to yield increasingly accurate population estimates, and managed harvest levels accordingly. Judging by this year's proposed Bear/Cougar Rule, it appears NMDGF has been right on the mark the last four years. The new rule calls for minor harvest increases in just two (of 14) Bear Management Zones, and a slight but overall decrease in cougar harvests. That's the result of science based management rather bending to the will of special interest groups -- some of whom would decimate both populations while others would allow them to expand to nuisance levels.

New Mexico should continue to manage predator populations based on good science, which includes regulated public hunting. Please adopt the proposed changes in bear and cougar regulations as proposed by NMDGF.

Thank you.

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Sir/ma'am,

I have a number of concerns regarding the new rules that are being considered to hunt bears and cougars for the next 4 years in New Mexico. My concerns include but are not limited to the below:

- Given the uncertainty of habitat and population estimates of both bears and cougars, the **quotas for both should be reduced**, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Killing bears and cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.
- New Mexico has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.

Thank you for your consideration of my concerns.

Very respectfully,

Stephanie Fuchs

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

- Too Whom it Concerns:
-
- Given the uncertainty of habitat and population estimates of both bears and cougars, the **quotas for both should be reduced**, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.
- Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures. Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.
- Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.
- The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these

species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent, outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.

- NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.
- Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.
- Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophies' and recreation. Ask NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

Thank you,

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Good morning New Mexico DFG representatives,

I am writing to support annual Bear and Cougar hunting.

New Mexico Department of Game and Fish biologists and Department management establish annual quota for hunting of Bears and Cougars and this practice needs to continue uninhibited by outside influences that are not supported by biologists, field studies, and NMDGF staff. Hunting is a natural part of all wildlife management and is proven to benefit species when conducted in association with wildlife studies and biologist evaluation of specie population and health.

Many hunters do not hunt Bear and Cougar with dogs, but I completely support the opportunity for hunters to use dogs while legally hunting for bear and cougar.

Thank you!

Richard Helgeson

Subject: [EXTERNAL] Bears and Cougars kill quotas
Date: Friday, July 14, 2023 2:37:36 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

- A respectful hello, please do not increase whatever your math shows that we can lose more bears and cougars. I think a few points that were brought up to me are valid and I hope you take a good look at these two points thank you
- NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.
- Scientifically rigorous studies of bears and cougars have recently been conducted in New Mexico, but the areas where data exist are very limited. Moreover, given the newness of these studies, they are only a snapshot of the current population in a given area. We do not yet have long-term on-the-ground field studies of bear and cougar populations throughout the state that could indicate population trends. Absent good data, the department should be exercising great caution with managing the population of bears and cougars.
-
-
- Finally the following point is one that is absolutely one that is hideous horrendous appalling and there is no way that this can be considered a sport: having dogs that have a better scent than a human, who is the one in the sport of hunting, the poor dogs don't know any better, treeing a poor animal and then shooting it at point blank. The poor bear or cougar didn't have a

fighting chance!!! This practice is just as disturbing as canned hunts. Please do not allow hunting of bears and cougars anymore only if a bear or cougar has been shown to be harmful to humans in the past. Thank you!

- Both bears and cougars are mostly hunted using dogs that chase them, following their scent until the exhausted animal seeks refuge and rest by climbing a tree. The hunter will then find the dogs, usually by using their electronic collar beacons as they keep the animal treed. When the hunter arrives at the scene, the hunter will shoot the animal at point blank range. Even segments of the hunting community find this practice contrary to Fair Chase hunting principles. Surveys of the general public also show opposition to killing bears and cougars using these methods for 'trophies' and recreation. Ask NM Game and Fish to consider broad public opinion and adopt hunting rules that ban the use of dogs in cougar and bear hunting.

Thank you for your time and consideration.

At this point in the earth's trajectory, bears and cougars constitute keystone species (not that any species are expendable) that must be protected to support the balance of a healthy ecology. Therefore the current quota proposals and potentially extended hunting seasons are inappropriate and must be reviewed by a team of qualified professionals.

How sad that the so-called recreation of humans is considered more important than the health of our ecosystem as a whole. We would do well to remember that we are as vulnerable as any other part of this system.

Sincerely,

Nodiah Brent

To whom it may concern

I am asking that you please lower the kill quotas for the Bears and Cougars and also to reduce the times for hunting seasons.

Animals have a right to be heard and people have a right to defend and have a say for animals. Bears and Cougars are self-

regulating, habitat loss and climate change has also not been counted as having any affects on them.

Conflicts happen between animals and people are due to the ignorance and stupidity of people. Killing for recreation and trophies just creates more issues.

I am also asking that you don't start the hunting seasons earlier and reduce the numbers as we need to also take into account the effects of draughts and wildfires in their populations.

The Department needs to be more transparent and truthful and protect the animals they are supposed to be out there protecting instead of doing the opposite...

Thank you for your time

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

Incredibly NM Fish & Game Dept. wants more dead bears and more dead cougars, in spite of persistent drought and forest fire destruction. Selling off wildlife as "products" is plain wrong. Hunter desires are ruling again. When will this stop? Now the agency wants to start the bear season in mid-August again. Huh? The dept. wants to kill up to a quarter of NM bears and cougars every year without any reason except to please hunters and in spite of not knowing how many of these animals actually exist in our state. Recreational killing for fun and trophies of the wildlife that belongs on NM landscapes is backward thinking. Soon there will be no more bears and cougars to kill.

The Fish and Game Dept. does not own our state's wildlife, but the majority of non-hunting New Mexicans have no real say in its wildlife policies. How about protecting bears and cougars for a change instead of allowing hunters to come first. The majority of New Mexicans appreciate our wildlife ALIVE. I oppose the current proposed rule changes.

To whom it may concern...

I know that you have received several emails requesting that you abolish the use of hounds and Bear / Cougar hunting in general. Considering our state has lost public land trapping, getting rid of hound hunting is a terrible idea. The states predator population is already a problem and was even before the trapping ban.

The use of hound hunting is essential to many ranchers to reduce the predator populations and instill a healthy fear of humans. Every state, without exception, that has banned hounds has suffered the consequences.

California is the perfect example.

One of the biggest lessons learned with the trapping ban is that compromising with anti groups does nothing but give them momentum. When the game department tried to bring trappers and anti groups together, trappers tried to find common ground to no avail. I beg you, please do not compromise.

Mike.

Dear Commissioners,

Protect cougar and bear hunting!! Each region boasts its unique challenges and merits when it comes to wildlife management. New Mexico's diverse ecosystems and longstanding hunting traditions demand policies tailored to its specific needs. Turning to evidence-based approaches and learning from the successes and failures of other regions will ensure a prosperous future for New Mexico's wildlife.

Sincerely,
James Sciacca

Dear Commissioners,

I'm writing in support of the cougar and bear hunts. The intricate web of ecosystem balance is maintained through various tools, with wildlife management being a crucial one. This isn't about favoring one group over another, but about understanding the symbiotic relationship between hunters, the game, and the larger ecosystem. The investment, both monetary and in terms of conservation efforts by hunters, has played a significant role in maintaining flourishing game populations. The challenge is to ensure that these efforts are recognized and not undermined by misconceptions or unscientific arguments.

Sincerely,
Dale Guillory

Dear Commissioners,

Keep the bear and cat hunts! It's essential to appreciate that every region has its unique ecological challenges and solutions. Drawing parallels with other states without understanding the underlying dynamics can be misleading. For instance, the consequences faced by states that banned certain hunting practices should serve as valuable lessons. Collaboration and understanding between various stakeholders can lead to informed decisions that are beneficial in the long run.

Sincerely,
Kyle Stangel

Dear Commissioners,

History has shown us that hunters have played an invaluable role in the conservation efforts of regions like New Mexico. Their contributions, both tangible and intangible, have bolstered game populations and fostered a culture of respect for the wild. It's pivotal that we recognize these efforts and ensure that they aren't undermined. Bear and cougar hunts? I'm in full support.

Sincerely,
Michael Embrey

Dear Commissioners,

Keep bear and cougar hunting in New Mexico! New Mexico's vision for wildlife management, emphasizing protection, regulation, and conservation, has always been forward-thinking. The proposed changes to the bear and cougar rule showcase a commitment to this vision. By aligning with these principles, New Mexico can ensure a sustainable future for its rich wildlife and the communities that depend on it.

Sincerely,
Brad Nickelson

Dear Commissioners,

New Mexico's dedication to wildlife protection, sustainable use, and conservation shines through its proposed bear and cougar rule changes. By adhering to these principles, New Mexico can continue to be a beacon of responsible wildlife management, ensuring that its unique ecosystems thrive for years to come. Protect the hunts!

Sincerely,
Glenn Steele

Dear Commissioners,

Wildlife management is not a one-size-fits-all domain. New Mexico, with its unique terrains and ecosystems, needs policies that are tailored to its distinct needs. Drawing from the vast reservoir of knowledge and research available, and blending it with the state's storied hunting traditions, ensures sustainable coexistence. Let the hunts continue!

Sincerely,
Trevor Moore

Subject: [EXTERNAL] Black Bears
Date: Sunday, August 20, 2023 12:12:56 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

I love the state of New Mexico and have stayed for months in Los Lunas and camped in the mountains that are right there. We had coyote visit our camp while we were sleeping and a black bear watched us from the other side of the creek for a couple of days. It was magical. The bears are sacred and need to be protected. But aside from my spiritual beliefs and sentiment, The Black Bear Bureau has kindly provided logical reasons not to expand the hunting season.

*Forest fires devastated thousands of acres and killed many bears and countless cubs who could not outrun the flames. With those deaths, combined with others such as;

* NMDGF kills, incidental kills (such as vehicle strikes, and predation kills where ranchers and others shoot bear on their land)

*Trophy hunting AKA "harvest" kills

The bear population, which is already in decline, will plummet further and faster.

- Given the uncertainty of habitat and population estimates of both bears and cougars, the quotas for both should be reduced, not raised. Kill quotas for both species have been unjustifiably high for many years.
- Bears and cougars are now known to be extremely important to the integrity of our ecosystems. Both species can self-regulate their own numbers. Therefore, erring on the side of killing fewer of these animals is not problematic. Killing too many can impact their populations for a long time.
- Killing Bears and Cougars at random for recreation and trophies does not help address conflict with humans. In fact, it may exacerbate conflict. Trophy hunters typically target larger, established individuals for their kills, disrupting important bear and cougar social structures.
- Bears and cougars are territorial animals, and if an individual who is not involved in conflict is killed, a younger and less experienced individual who is more prone to conflicts may move into the vacant territory.
- Bears and cougars are extremely hard to count accurately, so Game and Fish should exercise extreme caution when calculating kill quotas, to ensure the populations are not negatively affected. Current proposals to raise the kill quotas are reckless, don't apply the best available science, and ignore dangerously changing climate conditions. Adding more bear hunting permits and starting the season earlier in the heat of summer will likely result in more bears dying. This is both reckless and cruel.
- The hunting proposals lack scientific rigor. There is no management plan detailing measurable objectives for these species, and no attempt to address the uncertainty of the population estimates. Transparency is so lacking that the public has no way of knowing how the populations for either species have been derived. And there has been no external review of those population estimates by independent outside experts. In short, the hallmarks of good science, which the people of New Mexico deserve when it comes to wildlife management, are absent in the hunting rules proposed for bears and cougars.
- NM has recently experienced severe drought and wildfires, both of which will almost certainly continue and intensify into the next four years. There is no indication that NM Game and Fish has accounted for these factors in their habitat or population estimates. Our climate trends weigh in favor of lowering kill quotas, not raising them.

Please do the right thing.

With utmost sincerity,

Christina Mims.

I suggest New Mexico start managing wildlife based on science and not silly emotion. The use of hounds is an essential part of predator control, and make no mistake bears and cougars are apex predators.

Dear Commissioners,

Conservation and wildlife management practices are an evolving discipline that depends on both scientific data and historical context. The changes proposed in the bear and cougar rule reflect a dedication to this balance. The significant contributions made by hunters, anglers, trappers, and recreational shooters, not just in New Mexico but nationally, cannot be overstated. Prioritizing the insights of dedicated department biologists ensures a sustainable and healthy future for all wildlife.

Sincerely,
Clint Wood

Dear Commissioners,

Watching the fallout from the trapping ban has been a sobering experience. It underscores the dangers of compromising with groups that often seem to have a narrow focus. I hope we can stand firm against such pressures and maintain a holistic view of our state's ecosystem needs. Support the cougar and bear hunts!

Sincerely,
David Childers
